Modified Gauss-Newton scheme with worst-case guarantees for its global performance

Yu. Nesterov*

September 2003

Abstract

In this paper we suggest a new version of Gauss-Newton method for solving a system of nonlinear equations, which combines the idea of a sharp merit function with the idea of a quadratic regularization. For this scheme we prove general convergence results and, under a natural non-degeneracy assumption, a local quadratic convergence. We analyze the behavior of this scheme on some natural problem class, for which we get global and local worst-case complexity bounds. The implementation of each step of the scheme can be done by a standard convex optimization technique.

Keywords: Systems of nonlinear equations, Gauss-Newton method, trust-region methods, complexity bounds, global rate of convergence.

1 Introduction

Motivation. The problem of solving the systems of nonlinear equations is one of the most fundamental settings of numerical analysis. The reader can find the main achievements in this field and bibliographical comments in classical monographs [1, 2, 4, 6]. The standard approach to this problem consists in replacing the initial problem

\[ \text{Find } x \in \mathbb{R}^n : f_i(x) = 0, \quad i = 1, \ldots, m, \quad (1.1) \]

by a minimization problem

\[ \min_{x \in \mathbb{R}^n} \left[ f(x) \overset{\text{def}}{=} \phi(f_1(x), \ldots, f_m(x)) \right], \quad (1.2) \]

where the function \( \phi(u) \) is non-negative and vanishes only at the origin. The most recommended choice of the merit function \( \phi(u) \) is the standard squared Euclidean norm:

\[ \phi(u) = \| u \|^2 \equiv \sum_{i=1}^{m} (u^{(i)})^2, \quad (1.3) \]

where squaring the norm has the advantage of keeping the objective function in (1.2) smooth enough. Of course, the problem (1.2), (1.3) can be solved by the standard second-order minimization schemes. However, it is possible to reduce the order of the used derivatives by applying so-called Gauss-Newton method, in which the search direction is defined as a solution of the following auxiliary problem:

\[ \min_h \{ \phi(f_1(x) + \langle f'_1(x), h \rangle, \ldots, f_m(x) + \langle f'_m(x), h \rangle) : x + h \in D(x) \}, \]

where \( D(x) \) is a properly chosen neighborhood of point \( x \). Under some natural non-degeneracy assumptions, for this strategy it is possible to establish a local quadratic convergence (see, for example, [6], Section 10.2).

Despite to its elegance, the above mentioned approach deserves some criticism. Indeed, the transformation of problem (1.1) into the problem (1.2) is done in a quite dangerous way. For example, if our system of equations is linear, then such a transformation squares the condition number of the problem. Besides of increasing a numerical instability, for large problems this leads to squaring the number of iterations, which is necessary to get an \( \epsilon \)-solution of the initial problem.

In this paper we suggest another approach for solving the systems of non-linear equations. At the first glance, it looks very similar to the standard one: We replace our initial problem by a minimization problem (1.2), but with non-smooth merit function. For example, a possible choice would be \( \phi(u) = \| u \| \). Another difference is that at each iteration we compute the new test point as a minimizer of an auxiliary function, which is the sum of a “linearized” merit function with a quadratic proximal term. It appears that under natural assumptions for such a strategy it is possible to guarantee a monotone decrease of the non-smooth objective function in (1.2). In rather general situation we can establish a global and a local quadratic convergence of the scheme. Moreover, for some natural non-convex problem classes we manage to derive global complexity bounds. Note also that the majority of the papers in this field deal with a variant of problem (1.1) with
\[ m \geq n \] (that corresponds to a least-squares setting). In this paper the most interesting results (see Section 4) are obtained for \( m \leq n \), which is indeed a natural format for the systems of non-linear equations.

**Contents.** In Section 2 we define the modified Gauss-Newton step and prove its main properties. In Section 3 we present the modified Gauss-Newton method. We prove that any limit point of the process satisfies the first-order optimality conditions. If the solution of the system (1.1) possesses a (primal) non-degeneracy, then the convergence is quadratic. In the next Section 4 we study the class of problems with uniform *dual* non-degeneracy (see the end of this section for exact meaning of the terminology). Note that the problem from this class can have a continuous set of solutions; hence the corresponding Jacobians can be degenerate. Nevertheless, for this class of problems we establish a global efficiency estimate and prove a local quadratic convergence. In the last Section 5 we discuss the results. In Section 5.1 we compare the global efficiency of the modified Gauss-Newton method with that one of a modified Newton method proposed recently in [5]. In Section 5.2 we discuss the complexity of the auxiliary problems arising in the proposed scheme. We show that these problems can be solved by a standard technique developed for modern trust-region methods (see [1], Chapter 7).

**Notation.** For denoting the (primal) finite-dimensional linear vector spaces, we always use the letter \( E \), which may be marked by an index. This space is endowed with a fixed norm \( \| \cdot \| \), which is never indexed. Thus, in order to get the right sense of the notation \( \| x \| \), we need to take into account the space containing \( x \). This space is always well defined by a context. We denote by \( E^* \) the space of linear functions on \( E \). The value of \( s \in E^* \) on \( x \in E \) is denoted by \( \langle s, x \rangle \). The norms of the primal and dual spaces are related in a usual way:

\[ \| s \| = \max_{x \in E} \{ \langle s, x \rangle : \| x \| \leq 1 \}, \quad s \in E^*. \]

Thus, \( \langle s, x \rangle \leq \| s \| \cdot \| x \| \).

For a linear operator \( A : E_1 \to E_2 \), its *operator norm* \( \| A \| \) is introduced as

\[ \| A \| = \max_{x \in E_1} \{ \| Ax \| : \| x \| \leq 1 \}. \]

Again, the spaces \( E_1 \) and \( E_2 \) are always well defined by the context. For such an operator we introduce also the minimal singular value:

\[ \sigma_{\min}(A) = \min_{x \in E_1} \{ \| Ax \| : \| x \| = 1 \}. \]

If \( A \) is invertible, then \( \sigma_{\min}(A) = 1/\| A^{-1} \| \). Note that for two linear operators \( A_1 \) and \( A_2 \) we have

\[ \sigma_{\min}(A_1 A_2) \geq \sigma_{\min}(A_1) \cdot \sigma_{\min}(A_2). \]

If \( \sigma_{\min}(A) > 0 \), then we say that the operator \( A \) possesses a *primal non-degeneracy*.

Further, for a linear operator \( A : E_1 \to E_2 \) we denote by \( A^* \) its *adjoint*:

\[ \langle y, Ax \rangle \equiv \langle A^* y, x \rangle \quad \forall x \in E_1, \ y \in E_2^*. \]

Clearly, \( A^* \) maps \( E_2^* \) to \( E_1^* \). If \( \sigma_{\min}(A^*) > 0 \), then we say that \( A \) possesses a *dual non-degeneracy*. 

3
Finally, for a non-linear function $F(x) : E_1 \rightarrow E_2$ we denote by $F'(x)$ its Jacobian, which is a linear operator from $E_1$ to $E_2$:

$$F'(x)h = \lim_{\alpha \to 0} \frac{1}{\alpha} [F(x + \alpha h) - F(x)] \in E_2, \quad h \in E_1.$$ 

In the special case $f(x) : E_1 \rightarrow E_2 \equiv \mathbb{R}$, notation $f'(x)$ stays for the gradient of the function $f(x)$. In this case we treat $f'(x)$ as an element of $E^*$. For non-differentiable convex function $f(x)$ we denote by $\partial f(x)$ its subdifferential.

## 2 Modified Gauss-Newton iterate

Consider a smooth non-linear function $F(x) : E_1 \rightarrow E_2$. Our main problem of interest is to find an approximate solution to the following system of equations:

$$F(x) = 0, \quad x \in E_1. \quad (2.1)$$

In order to measure the quality of such a solution, we introduce a (sharp) merit function $\phi(u), u \in E_2$, which satisfies the following conditions:

- It is convex, non-negative and vanishes only at the origin. (Hence, its level sets are bounded.)
- It is Lipschitz-continuous with unitary Lipschitz constant:
  $$|\phi(u) - \phi(v)| \leq \|u - v\|, \quad \forall u, v \in E_2.$$
- It has a sharp minimum at the origin:
  $$\phi(u) \geq \gamma_\phi \|u\|, \quad \forall u \in E_2, \quad (2.2)$$
  for a certain $\gamma_\phi \in (0, 1]$.

For example, we can take $\phi(u) = \|u\|$. Then $\gamma_\phi = 1$.

We can use this merit function for transforming the problem (2.1) into the following unconstrained minimization problem:

$$\min_{x \in E_1} \{ f(x) \equiv \phi(F(x)) \} \overset{\text{def}}{=} f^*. \quad (2.3)$$

Clearly, the solution $x^*$ to the system (2.1) exists if and only if the optimal value $f^*$ in the problem (2.3) is equal to zero. The iterative scheme proposed below can be seen as a minimization method for problem (2.3), which employs a special structure of the objective function. Function $f(x)$ can be even non-smooth. However, we will see that it is possible to decrease its value at any $x$ from $E_1$ excluding the stationary points of (2.3).

Let us fix some $x \in E_1$. Consider the following local model of our objective function:

$$\psi(x; y) = \phi \left( F(x) + F'(x)(y - x) \right), \quad y \in E_1.$$ 

Note that $\psi(x; y)$ is convex in $y$. Therefore it looks natural to choose the next approximation to the solution of (2.3) from the set

$$\text{Arg min}_{y \in E_1} \psi(x; y).$$
Such schemes are very well studied in the literature (see [1], [2], [4], [6]). For example, if we take
\[ \phi(u) = \left[ \sum_{i=1}^{m} (u^{(i)})^{2} \right]^{1/2}, \quad u \in \mathbb{R}^{m}, \]
then we get a classical Gauss-Newton method. However, in what follows we argue that a simple regularization of this approach allows us to get a new scheme, for which we can speak about a global efficiency of the process.

We need to introduce the following smoothness assumption. Let \( F \) be a closed convex set in \( E_{1} \) with non-empty interior.

**Assumption 1** Function \( F(x) \) is differentiable on \( F \) and its derivative is Lipschitz-continuous:
\[ \| F'(x) - F'(y) \| \leq L \| x - y \|, \quad \forall x, y \in F, \]
with some \( L > 0 \).

In what follows we always assume that Assumption 1 is satisfied.

**Lemma 1** For any \( x \) and \( y \) from \( F \) we have
\[ |f(y) - \psi(x; y)| \leq \frac{1}{2}L \| y - x \|^2. \] (2.5)

**Proof:**
Denote \( d(x, y) = F(y) - F(x) - F'(x)(y - x) \in E_{2} \). By Proposition 3.2.12 in [4],
\[ \| d(x, y) \| \leq \frac{1}{2}L \| x - y \|^2. \]
Hence, since both \( x \) and \( y \) belong to \( F \), we have
\[ |f(y) - \psi(x; y)| = |\phi(F(y)) - \phi(F(x) + F'(x)(y - x))| \leq \| d(x, y) \| \leq \frac{1}{2}L \| y - x \|^2. \]

\( \square \)

Inequality (2.5) provides us with an upper approximation of the function \( f(x) \):
\[ f(y) \leq \psi(x; y) + \frac{1}{2}L \| y - x \|^2, \quad \forall x, y \in F. \]

Let us use it for constructing a minimization scheme. Let \( M \) be a positive parameter. For the problem (2.3), define a *modified Gauss-Newton iterate* from a point \( x \in F \) as follows:
\[ V_{M}(x) \in \text{Arg min}_{y \in E_{1}} \left[ \psi(x; y) + \frac{1}{2}M \| y - x \|^2 \right], \]
(2.6)
where "Arg" indicates that \( V_{M}(x) \) is chosen from the set of global minima of the corresponding minimization problem.\(^1\) Note that the auxiliary optimization problem in (2.6) is convex in \( y \). We postpone a discussion on the complexity of finding \( V_{M}(x) \) up to Section 5.

\(^1\)Since we do not assume that the norm \( \| x \|, x \in E_{1} \), is strongly convex, this problem may have a non-trivial set of global solutions.
Let us prove several auxiliary results. Denote
\[ r_M(x) = \|V_M(x) - x\|, \]
\[ f_M(x) = \psi(x; V_M(x)) + \frac{1}{2} Mr_M^2(x), \]
\[ \delta_M(x) = f(x) - f_M(x). \]

Note that for \( x \) being fixed, \( f_M(x) \) is concave in \( M \):
\[ f_M(x) = \min_{y \in E_1} \left[ \psi(x; y) + \frac{1}{2} M \|y - x\|^2 \right]. \]

Consequently, the value \( \frac{1}{2} r_M^2(x) \), which is equal to the derivative of \( f_M(x) \) in \( M \), is a decreasing function of \( M \).

**Lemma 2** For any \( x \in E_1 \) we have
\[ \delta_M(x) \geq \frac{1}{2} Mr_M^2(x). \] (2.7)

**Proof:**
Let us fix an arbitrary \( x \in E_1 \). Consider the function
\[ \xi(t) = \min_{y \in E_1} \left[ \phi(F(x) + F'(x)(y - x)) + \frac{1}{2t} \|y - x\|^2 \right]. \] (2.8)

Note that the set \( \{(y, t, \alpha) \in E_1 \times R^2_+: \|y - x\| \leq (\alpha t)^{1/2}\} \) is convex. Consequently, the objective function of optimization problem in (2.8) is jointly convex in \((y, t)\). Therefore the function \( \xi(t) \) is convex in \( t \) and
\[ g(t) = -\frac{1}{2t^2} r_{1/t}^2(x) \in \partial \xi(t). \]

Therefore,
\[ f(x) = \xi(0) \geq \xi(t) + g(t) \cdot (-t) = \xi(t) + \frac{1}{2t^2} r_{1/t}^2(x). \]

Since \( \xi(1/M) = f_M(x) \), we get (2.7). \( \square \)

Let us compare \( \delta_M(x) \) with another natural measure of local decrease of the model \( \psi(x; \cdot) \). For \( r > 0 \) denote
\[ \Delta_r(x) = f(x) - \min_{y \in E_1} \{ \psi(x; y) : \|y - x\| \leq r \}. \]

**Lemma 3** For any \( x \in E_1 \) and \( r > 0 \) we have
\[ \delta_M(x) \geq Mr^2 \cdot \kappa \left( \frac{1}{Mr^2} \Delta_r(x) \right), \] (2.9)

where
\[ \kappa(t) = \begin{cases} 
  t - \frac{1}{2}, & t \geq 1, \\
  \frac{1}{2} t^2, & t \in [0, 1]. 
\end{cases} \]

The right-hand side of the bound (2.9) is a decreasing function of \( M \).
Proof:
Let us choose \( h_r \in \text{Arg } \min \{ \psi(x; x + h) : \|h\| \leq r \} \). Then
\[
\begin{align*}
    f_M(x) &\leq \min_{\tau} \{ \phi(F(x) + \tau F'(x) h_r) + \frac{1}{2} M \tau^2 r^2 : \tau \in [0, 1] \} \\
    &= \min_{\tau} \{ \phi((1 - \tau)F(x) + \tau(F(x) + F'(x) h_r)) + \frac{1}{2} M \tau^2 r^2 : \tau \in [0, 1] \} \\
    &\leq \min_{\tau} \{ (1 - \tau)\phi(F(x)) + \tau \phi(F(x) + F'(x) h_r) + \frac{1}{2} M \tau^2 r^2 : \tau \in [0, 1] \} \\
    &= \min_{\tau} \{ f(x) - \tau \Delta_r(x) + \frac{1}{2} M \tau^2 r^2 : \tau \in [0, 1] \}.
\end{align*}
\]
Thus,
\[
\delta_M(x) \geq \max_{\tau \in [0, 1]} \{ \tau \Delta_r(x) - \frac{1}{2} M \tau^2 r^2 \} = M r^2 \cdot \kappa \left( \frac{1}{M^{\tau^2}} \Delta_r(x) \right).
\]
Note that the right-hand side of this inequality is decreasing in \( M \). \( \Box \)

Denote
\[ \mathcal{L}(\tau) = \{ y \in E_1 : f(y) \leq \tau \}. \]

Lemma 4 Let \( \mathcal{L}(f(x)) \subseteq \text{int } \mathcal{F} \) and \( M \geq L \). Then \( V_M(x) \in \mathcal{L}(f(x)) \).

Proof:
Assume \( V_M(x) \notin \mathcal{L}(f(x)) \). Consider the points
\[ y(\alpha) = x + \alpha \cdot (V_M(x) - x), \quad \alpha \in [0, 1]. \]
Since \( y(0) = x \in \text{int } \mathcal{F} \), we can define the value \( \bar{\alpha} \in (0, 1) \) such that \( y(\bar{\alpha}) \) lies on the boundary of the set \( \mathcal{F} \). Note that
\[ f(y(\bar{\alpha})) \geq f(x) \geq f_M(x), \]
and \( r_M(x) > 0 \). In accordance to our assumption, \( \bar{\alpha} \in (0, 1) \). Denote
\[ d = F(y(\bar{\alpha})) - F(x) - \bar{\alpha} F'(x)(V_M(x) - x) \in E_2. \]
In view of Proposition 3.2.12 in [4], \( \|d\| \leq \frac{L}{2} \bar{\alpha}^2 r_M^2(x) \). Therefore,
\[
\begin{align*}
    f(x) &\leq f(y(\bar{\alpha})) \leq \phi(F(x) + \bar{\alpha} F'(x)(y - x) + d) \\
    &\leq \phi((F(x) + \bar{\alpha} F'(x)(V_M(x) - x)) + \|d\| \leq (1 - \bar{\alpha}) f(x) + \bar{\alpha} \phi((F(x) + F'(x)(V_M(x) - x)) + \frac{1}{2} M \bar{\alpha}^2 r_M^2(2) \\
    &\leq (1 - \bar{\alpha}) f(x) + \bar{\alpha} f_M(x) - \frac{1}{2} M \bar{\alpha} (1 - \bar{\alpha}) r_M^2(x) \leq f_M(x) - \frac{1}{2} M (1 - \bar{\alpha}) r_M^2(x), \quad \text{and that is a contradiction to (2.7)}. \( \Box \)
Lemma 5 Let both $x$ and $V_M(x)$ belong to $\mathcal{F}$. Then

$$f_M(x) \leq \min_{y \in \mathcal{F}} \left[ f(y) + \frac{1}{2}(L + M)\|y - x\|^2 \right].$$ \hfill (2.10)

Proof: For $y \in \mathcal{F}$ denote $d(x, y) = F(y) - F(x) - F'(x)(y - x) \in E_2$. By Proposition 3.2.12 [4],

$$\|d(x, y)\| \leq \frac{1}{2}L \|x - y\|^2.$$

Hence, since both $x$ and $V_M(x)$ belong to $\mathcal{F}$, we have

$$f_M(x) = \min_{y \in \mathcal{F}} \left[ \phi(F(x) + F'(x)(y - x)) + \frac{1}{2}M\|y - x\|^2 \right]$$

$$= \min_{y \in \mathcal{F}} \left[ \phi(F(y) - d(x, y)) + \frac{1}{2}M\|y - x\|^2 \right]$$

$$\leq \min_{y \in \mathcal{F}} \left[ f(y) + \frac{1}{2}(L + M)\|y - x\|^2 \right].$$

\[\square\]

Corollary 1 Let $x^*$ be a solution to the problem (2.3) and $\mathcal{L}(f(x)) \subseteq \mathcal{F}$. Then

$$f_M(x) \leq f^* + \frac{1}{2}(L + M)\|x - x^*\|^2.$$ \hfill (2.11)

Proof: It is enough to substitute $y = x^*$ in the right-hand side of (2.10). \hfill \[\square\]

3 Modified Gauss-Newton process

Now we can analyze convergence of the following process. Let us fix some $L_0 \in (0, L]$.

<table>
<thead>
<tr>
<th>Modified Gauss-Newton method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initialization: Choose $x_0 \in \mathbb{R}^n$.</td>
</tr>
<tr>
<td>Iteration $k$, ($k \geq 0$):</td>
</tr>
<tr>
<td>1. Find $M_k \in [L_0, 2L]$ such that $f(V_{M_k}(x_k)) \leq f_{M_k}(x_k)$.</td>
</tr>
<tr>
<td>2. Set $x_{k+1} = V_{M_k}(x_k)$.</td>
</tr>
</tbody>
</table>
Since \( f_M(x) \leq f(x) \), this process is monotone:

\[
f(x_{k+1}) \leq f(x_k). \tag{3.2}
\]

If the constant \( L \) is known, then in Item 1 of this scheme we can use \( M_k \equiv L \). In the opposite case, it is possible to apply a simple search procedure. The reader could consult [5], Section 5.2, where two efficient strategies are discussed for a similar optimization scheme. Let us present now the convergence results.

Let \( x_0 \in \text{int } F \) be a starting point for the above minimization process. We need to assume the following.

**Assumption 2** The set \( F \) is big enough: \( \mathcal{L}(f(x_0)) \subseteq F \).

In what follows we always suppose Assumption 2 be satisfied. In view of (3.2) this assumption implies that \( \mathcal{L}(f(x_k)) \subseteq F \) for any \( k \geq 0 \).

**Theorem 1** For any \( k \geq 0 \) and \( r > 0 \) we have

\[
f(x_k) - f^* \geq \frac{1}{2} L_0 \sum_{i=k}^{\infty} r^2_{M_i}(x_i) \geq \frac{1}{2} L_0 \sum_{i=k}^{\infty} r^2_{2L}(x_i),
\]

\[
f(x_k) - f^* \geq r^2 \sum_{i=k}^{\infty} M_i \kappa \left( \frac{1}{M_i} \Delta_r(x) \right) \geq 2Lr^2 \sum_{i=k}^{\infty} \kappa \left( \frac{1}{2Lr^2} \Delta_r(x) \right). \tag{3.3}
\]

**Proof:**
Indeed, in view of the rules of Item 1 in (3.1),

\[ f_M(x_i) \geq f(x_{i+1}), \quad M_i \geq L_0, \quad r_M(x_i) \geq r_{2L}(x_i). \]

Thus, inequality (2.7) justifies the first inequality in (3.3). In order to prove the second one, we apply (2.9) and use the bound \( M_i \leq 2L \) imposed by (3.1).

**Corollary 2** Let the sequence \( \{x_k\}_{k=0}^{\infty} \) be generated by the scheme (3.1). Then

\[
\lim_{k \to \infty} \|x_k - x_{k+1}\| = 0, \quad \lim_{k \to \infty} \Delta_r(x_k) = 0,
\]

and therefore the set of limit points \( X^* \) of this sequence is connected. For any \( \bar{x} \) from \( X^* \) we have \( \Delta_r(\bar{x}) = 0 \).

Let us justify now the local convergence of the scheme (3.1).

**Theorem 2** Let point \( x^* \in \mathcal{L}(f(x_0)) \) with \( F(x^*) = 0 \) be a non-degenerate solution to problem (2.1):

\[ \sigma \equiv \sigma_{\text{min}}(F'(x^*)) > 0. \]

If \( x_k \in \mathcal{L}(f(x_0)) \) and \( \|x_k - x^*\| \leq \frac{2}{L} \cdot \frac{\sigma_{\gamma_0}}{3+5\gamma_0} \), then \( x_{k+1} \in \mathcal{L}(f(x_0)) \) and

\[
\|x_{k+1} - x^*\| \leq \frac{3(1+\gamma_0)L\|x_k-x^*\|^2}{2\gamma_0(\sigma-L\|x_k-x^*\|)} \leq \|x_k - x^*\|. \tag{3.4}
\]
Proof:
Since \( f(x^*) = 0 \), in view of inequality (2.11) and Proposition 3.2.12 [4], we have
\[
\frac{3L}{2}\|x_k - x^*\|^2 \geq f_M(x_k) \geq \psi(x_k; x_{k+1}) \geq \gamma_\phi \|F(x_k) + F'(x_k)(x_{k+1} - x_k)\|
\]
\[
= \gamma_\phi \|F'(x^{*})(x_{k+1} - x^*) + (F(x_k) - F(x^*) - F'(x^*)(x_k - x^*))
\]
\[
+ (F'(x_k) - F'(x^*))((x_{k+1} - x_k))\|
\]
\[
\geq \gamma_\phi \left[ \|F'(x^{*})(x_{k+1} - x^*)\| - \frac{L}{2}\|x_k - x^*\|^2 - L\|x_k - x^*\| \cdot \|x_{k+1} - x_k\| \right]
\]
\[
\geq \gamma_\phi \left[ (\sigma - L\|x_k - x^*\|) \cdot \|x_{k+1} - x^*\| - \frac{3L}{2}\|x_k - x^*\|^2 \right].
\]

\[\square\]

4 Global rate of convergence

In order to get global complexity results for method (3.1), we need to introduce an additional non-degeneracy assumption.

**Assumption 3** The operator \( F'(x) : E_1 \to E_2 \) possesses a uniform dual non-degeneracy:
\[
\sigma_{\min}(F'(x^*)) \geq \sigma > 0 \quad \forall x \in \mathcal{L}(f(x_0)).
\]

Note that this assumption implies \( \dim E_2 \leq \dim E_1 \). The role of Assumption 3 in our analysis can be seen from the following result.\(^2\)

**Lemma 6** Let linear operator \( A : E_1 \to E_2 \) possess dual non-degeneracy: \( \sigma_{\min}(A^*) > 0 \). Then for any \( b \in E_2 \) there exists a point \( x(b) \in E_1 \) such that
\[
Ax(b) = b, \quad \|x(b)\| \leq \frac{\|b\|}{\sigma_{\min}(A^*)}.
\]

**Proof:**
Indeed, for any \( r > 0 \) we have
\[
\max_{\|b\| \leq r} \min_{x \in E_1} \{\|x\| : Ax = b\} = \max_{\|b\| \leq r} \min_{x \in E_1} \max_{s \in E_2^*} \{\|x\| + \langle s, b - Ax \rangle\} = \max_{\|b\| \leq r} \max_{s \in E_2^*} \min_{x \in E_1} \{\|x\| + \langle s, b - Ax \rangle\} = \max_{\|b\| \leq r} \max_{s \in E_2^*} \{\langle s, b \rangle : \|A^*s\| \leq 1\} = \max_{s \in E_2^*} \{r \|s\| : \|A^*s\| \leq 1\} = \frac{r}{\sigma_{\min}(A^*)}.
\]

An important consequence of Lemma 6 is as follows.

\(^2\)Different variants of this statement are widespread in the literature. Its most general form can be found in [3]. We provide this statement with a simple proof for the reader’s convenience.
Lemma 7 Let the operator $F'(x)$ possess a dual non-degeneracy: $\sigma_{\min}(F'(x)^*) > 0$. Then for any $M > 0$ we have

$$ r_M(x) \leq \frac{\|F(x)\|}{\sigma_{\min}(F'(x)^*)}. \tag{4.1} $$

Proof:
Indeed, in view of Lemma 6 there exists $h^*$ such that $F(x) + F'(x)h^* = 0$ and

$$ \|h^*\| \leq \frac{\|F(x)\|}{\sigma_{\min}(F'(x)^*)}. $$

Therefore

$$ \frac{M}{2} r_M^2(x) \leq \psi(x; V_M(x)) + \frac{M}{2} r_M^2(x) = \min_{h \in E_1} [\psi(x; x + h) + \frac{M}{2} \|h\|^2] \leq \frac{M}{2} \|h^*\|^2 \leq \frac{M\|F(x)\|^2}{2\sigma_{\min}(F'(x)^*)}. $$. 

Now we can justify the global rate of convergence of scheme (3.1).

Theorem 3 Let Assumptions 1, 2 and 3 be satisfied.

1). Suppose that the sequence $\{x_k\}_{k=0}^\infty$ be generated by method (3.1). If $f(x_k) \geq \frac{\sigma^2}{2L\gamma_0}$, then

$$ f(x_{k+1}) \leq f(x_k) - \frac{\sigma^2}{2L\gamma_0}. \tag{4.2} $$

Otherwise,

$$ f(x_{k+1}) \leq \frac{L}{2\sigma^2\gamma_0} f^2(x_k) \leq \frac{1}{2} f(x_k). \tag{4.3} $$

2). Suppose that the sequence $\{x_k\}_{k=0}^\infty$ be generated by method (3.1) with $M_k \equiv L$. If $f(x_k) \geq \frac{\sigma^2}{L\gamma_0}$, then

$$ f(x_{k+1}) \leq f(x_k) - \frac{\sigma^2}{2L\gamma_0}. \tag{4.4} $$

Otherwise,

$$ f(x_{k+1}) \leq \frac{L}{2\sigma^2\gamma_0} f^2(x_k) \leq \frac{1}{2} f(x_k). \tag{4.5} $$

Proof:
Let us prove the first part of the theorem. Since the operator $F'(x_k)$ is non-degenerate, in view of Lemma 6 there exists a solution $h^*_k$ to the system of linear equations $F(x_k) + F'(x_k)h = 0$ with a bounded norm:

$$ \|h^*_k\| \leq \frac{1}{\sigma} \|F(x_k)\| \leq \frac{1}{\sigma\gamma_0} f(x_k). $$
Therefore, in view of the step-size rules in the scheme (3.1) and the upper bound on the values $M_k$, we have
\[
f(x_{k+1}) \leq \min_{h \in E_1} \left[ \phi(F(x_k) + F'(x_k)h) + \frac{1}{2} M_k \|h\|^2 \right] \]
\[
\leq \min_{t \in [0,1]} \left[ \phi(F(x_k) + tF'(x_k)h^*_k) + L \|t h^*_k\|^2 \right] \]
\[
\leq \min_{t \in [0,1]} \left[ \phi((1-t)F(x_k)) + \frac{L}{\sigma^2 \gamma^2_{\phi}} t^2 f^2(x_k) \right] \]
\[
\leq \min_{t \in [0,1]} \left[ (1-t)f(x_k) + \frac{L}{\sigma^2 \gamma^2_{\phi}} t^2 f^2(x_k) \right] \]

Thus, if $f(x_k) \leq \frac{\sigma^2}{2L} \gamma^2_{\phi}$, then the minimum in the latter one-dimensional problem is attained at $t = 1$ and we get inequalities (4.3). In the opposite case, the minimum is attained at $t = \frac{\sigma^2 \gamma^2_{\phi}}{2L f(x_k)}$ and we get estimate (4.2).

The second part of the theorem can be proved in a similar way. $\square$

Using Theorem 3, we can establish some properties of the problem (2.3).

**Theorem 4** Let Assumptions 1, 2 and 3 be satisfied. Then there exists a solution $x^*$ to the problem (2.3) such that
\[
f(x^*) = 0 \quad \text{and} \quad \|x^* - x_0\| \leq \frac{2}{\sigma} \|F(x_0)\|. \quad (4.6)\]

**Proof:**
Let us choose $\phi(u) = \|u\|$. Then $\gamma_{\phi} = 1$. Let us apply now method (3.1) with $M_k \equiv L$ to corresponding problem (2.3) with $f(x) = \|F(x)\|$.

Assume first, that $f(x_0) > \frac{\sigma^2}{L}$. In accordance to the second statement of Theorem 3, as far as $f(x_k) \geq \frac{\sigma^2}{L}$ we have
\[
f(x_k) - f(x_{k+1}) \geq \frac{\sigma^2}{2L}. \quad (4.7)\]

Denote by $N$ the length of the first stage of the process:
\[
f(x_N) \geq \frac{\sigma^2}{L} \geq f(x_{N+1}). \quad (4.8)\]

Summing up inequalities (4.7) for $k = 0, \ldots, N$, we get
\[
N + 1 \leq \frac{2L}{\sigma^2}(f(x_0) - f(x_{N+1})). \quad (4.9)\]

On the other hand, in view of inequality (2.7) we have
\[
f(x_k) - f(x_{k+1}) \geq \frac{L}{2} \|x_k - x_{k+1}\|^2. \quad (4.10)\]

Summing up these inequalities for $k = 0, \ldots, N$, we get
\[
f(x_0) - f(x_{N+1}) \geq \frac{L}{2} \sum_{k=0}^{N} \|x_k - x_{k+1}\|^2 \geq \frac{L}{2(N+1)} \left( \sum_{k=0}^{N} \|x_k - x_{k+1}\| \right)^2 \]
\[
\geq \frac{L}{2(N+1)} \|x_0 - x_{N+1}\|^2. \quad (4.11)\]

12
Now, using the estimate (4.8), we obtain
\[
\|x_0 - x_{N+1}\| \leq \left[ \frac{2(N+1)}{L} (f(x_0) - f(x_{N+1})) \right]^{1/2} \leq \frac{2}{\sigma} (f(x_0) - f(x_{N+1})).
\] (4.10)

Further, in view of Theorem 3, at the second stage of the process we can guarantee that
\[
f(x_{k+1}) \leq \frac{L}{2\sigma^2} f^2(x_k) \leq \frac{1}{2} f(x_k), \quad k \geq N + 1.
\] (4.11)
Thus, \(f(x_{N+k+1}) \leq \left(\frac{1}{2}\right)^k f(x_{N+1})\) for \(k \geq 0\). Hence, in view of inequality (4.1) we have
\[
\|x_{N+k+2} - x_{N+k+1}\| \leq \frac{1}{\sigma} \left(\frac{1}{2}\right)^k f(x_{N+1}), \quad k \geq 0.
\]
Thus, the sequence \(\{x_k\}_{k=0}^{\infty}\) converges to a point \(x^*\) with \(F(x^*) = 0\) and
\[
\|x^* - x_{N+1}\| \leq \frac{2}{\sigma} f(x_{N+1}).
\]

Taking into account this inequality and (4.10), we get (4.6).

If \(f(x_0) \leq \frac{\sigma^2}{L}\), then we can apply the latter reasoning from the very beginning:
\[
\sum_{k=0}^{\infty} \|x_{k+1} - x_k\| \leq \frac{1}{\sigma} \sum_{k=0}^{\infty} f(x_k) \leq \frac{1}{\sigma} f(x_0) \sum_{k=0}^{\infty} \left(\frac{1}{2}\right)^k = \frac{2}{\sigma} f(x_0).
\]
\(\square\)

Applying exactly the same arguments as in the proof of Theorem 4, it is possible to justify the following statement.

**Theorem 5** Let Assumptions 1, 2 and 3 be satisfied. Suppose the sequence \(\{x_k\}_{k=0}^{\infty}\) be generated by method (3.1) as applied to the problem (2.3). Then this sequence converges to a single point \(x^*\) with \(F(x^*) = 0\). \(\square\)

Let us conclude this section with the following remark. We have seen that Assumptions 1, 2 and 3 guarantee existence of a solution to the problem (2.1). Denote
\[
D = \min_x \{\|x - x_0\| : x \in \mathcal{L}(f(x_0)), \ F(x) = 0\}.
\]

In view of Corollary 1 and the bounds on \(M_k\) in method (3.1), we can always guarantee that
\[
f(x_1) \leq \frac{3}{2} LD^2.
\] (4.12)
Thus, in view of Theorem 3, the number of iterations \(N\) of method (3.1), which is necessary in order to reach the region of quadratic convergence can be bounded as follows:
\[
N \leq 1 + \frac{4L}{\sigma^2} f(x_1) \leq 1 + 6 \left(\frac{LD}{\sigma}\right)^2.
\] (4.13)

We will refer to this bound as to an upper complexity estimate of the class of problems described by Assumptions 1, 2 and 3. This bound is justified by the modified Gauss-Newton method (3.1).
5 Discussion

5.1 Comparative analysis of the scheme (3.1)

For other methods proposed so far for solving the systems of non-linear equations, we did not manage to find in the literature any global worst-case efficiency estimates. Therefore we have to compare the efficiency of method (3.1) with the only general-purpose scheme, for which such estimates are known. That is a modified Newton scheme for unconstrained minimization proposed recently in [5]. Note that the fields of applications of both methods intersect. Indeed, any problem of solving a system of non-linear equations can be transformed into a problem of unconstrained minimization using a kind of merit function. On the other hand, any unconstrained minimization problem can be reduced to a system of non-linear equations, which correspond to the first-order optimality conditions.

Consider the following unconstrained minimization problem:

\[ \min_{x \in E_1} \varphi(x), \]  

(5.1)

where \( \varphi(x) \) is a twice differentiable strongly convex function, which Hessian is Lipschitz continuous. Thus, we assume that there exist positive \( \sigma \) and \( L \) such that the conditions

\[ \langle \varphi''(x) h, h \rangle \geq \sigma \| h \|^2, \]

\[ \| \varphi''(x + h) - \varphi''(x) \| \leq L \| h \|, \]

are satisfied for any \( x \) and \( h \) from \( E_1 \). Denote \( D = \| x_0 - x^* \| \). Then in [5], Section 6, it is shown that the complexity of the problem (5.1) for the modified Newton method (3.3)[5] depends on the characteristic

\[ \zeta = \frac{LD}{\sigma} \]

(we use notation of our paper). If \( \zeta < 1 \), then the problem (5.1) is easy. In the opposite case, the number of iterations of the modified Newton scheme, which is necessary in order to come to the region of quadratic convergence, is bounded by

\[ N_1 = 6.25 \sqrt{\zeta}, \]

(5.3)

(see (6.1) in [5]).

Note that the problem (5.1) can be posed in the form (2.1):

\[ \text{Find } x : \ F(x) \overset{\text{def}}{=} \varphi'(x) = 0. \]  

(5.4)

Note that \( F'(x) = \varphi''(x) \). Therefore, in view of conditions (5.2), our problem (5.4) satisfies Assumptions 1, 2 and 3. Let us choose \( f(x) = \| F(x) \| \). Then, in view of (4.13), the number of iterations of the modified Gauss-Newton scheme (3.1), which is necessary in order to come to the region of quadratic convergence, is bounded by

\[ N_2 = 1 + 6\zeta^2. \]

(5.5)

Clearly, the estimate (5.3) is much better than (5.5). However, this observation just confirms a standard rule that a specialized procedure must be more efficient than a general purpose scheme. The question is: How much? Needless to say that at this moment
we know nothing about lower complexity bounds of the problem class described by Assumptions 1, 2 and 3. So, there are chances that the complexity (5.5) can be improved by another methods.

In fact, as compared with the modified Newton method [5], the scheme (3.1) has one important advantage. The auxiliary problem of computation of the new test point at each iteration of the modified Newton method [5] is solvable in polynomial time only if this method is based on a Euclidean norm. On the contrary, in the modified Gauss-Newton scheme we are absolutely free in the choice of the norms in the spaces $E_1$ and $E_2$. As we will see in Section 5.2, any choice results in a convex auxiliary problem. Therefore the norms can be chosen in a reasonable way, which makes the ratio $\frac{L}{\sigma}$ as small as possible.

5.2 Implementation issues

Let us study the complexity of the auxiliary problem (2.6). For simplicity, let us assume that we choose $f(x) = \|F(x)\|$. So, our problem becomes as follows:

Find $f_M(x) = \min_{h \in E_1} \left[ \|F(x) + F'(x)h\| + \frac{1}{2} M \|h\|^2 \right]$.

(5.6)

Note that sometimes this problem looks easier in its dual form:

$$\min_{h \in E_1} \left[ \|F(x) + F'(x)h\| + \frac{1}{2} M \|h\|^2 \right] = \min_{h \in E_1} \max_{\|s\| \leq 1} \left[ \langle s, F(x) + F'(x)h \rangle + \frac{1}{2} M \|h\|^2 \right]$$

$$= \max_{\|s\| \leq 1} \min_{h \in E_1} \left[ \langle s, F(x) + F'(x)h \rangle + \frac{1}{2} M \|h\|^2 \right]$$

$$= \max_{\|s\| \leq 1} \left[ \langle s, F(x) \rangle - \frac{1}{2M} \|F'(x)s\|^2 : \|s\| \leq 1 \right].$$

(5.7)

Thus, the problem dual to (5.6) is just a quadratic maximization problem with simple constraints:

$$\max_{(s,\tau) \in E_2 \times R} \left[ \langle s, F(x) \rangle - \frac{\tau^2}{2M} : \|s\| \leq 1, \|F'(x)s\| \leq \tau \right].$$

(5.7)

This is a convex problem, which can be solved by the efficient standard methods.

Let us show that in the case of Euclidean norms, the problem (5.6) can be solved by a standard linear algebra technique.

Lemma 8 Let us introduce in $E_1$ and $E_2$ some Euclidean norms:

$$\|x\| = \langle Q_1 x, x \rangle^{1/2}, x \in E_1, \quad \|u\| = \langle Q_2 u, u \rangle^{1/2}, u \in E_2.$$  

Then the problem (5.6) can be represented in a dual form as follows:

$$f_M(x) = \min_{\lambda \in R} \left[ \frac{1}{2} \lambda + \frac{1}{2} \left( \langle \lambda Q_2 + \frac{1}{M} F'(x)Q_1^{-1}F'(x)^* - 1 F(x), F(x) \rangle : \lambda \geq 0 \right) \right].$$

(5.8)

If $\lambda^*$ is an optimal solution to this problem, then the solution to (5.6) is given by

$$h^* = -\frac{1}{M}Q_1^{-1}F'(x)^* \left( \lambda^* Q_2 + \frac{1}{M} F'(x)Q_1^{-1}F'(x)^* \right)^{-1}F(x).$$

(5.9)
Proof:
Indeed

\[ f_M(x) = \min_{h \in E_1} \max_{s \in E_2} \left[ \langle s, F(x) + F'(x)h \rangle + \frac{M}{2} \langle Q_1 h, h \rangle : \langle s, Q_2 s \rangle \leq 1 \right] \]

\[ = \max_{s \in E_2} \left[ \langle s, F(x) \rangle - \frac{1}{2M} \langle Q_1^{-1} F'(x)^* s, F'(x)^* s \rangle : \langle s, Q_2 s \rangle \leq 1 \right] \]

\[ = \max_{s \in E_2} \min_{\lambda \geq 0} \left[ \langle s, F(x) \rangle - \frac{1}{2M} \langle Q_1^{-1} F'(x)^* s, F'(x)^* s \rangle + \frac{1}{2} \lambda (1 - \langle s, Q_2 s \rangle) \right] \]

\[ = \min_{\lambda \geq 0} \left[ \frac{1}{2} \lambda + \frac{1}{2} \left( \langle \lambda Q_2 + \frac{1}{M} F'(x)Q_1^{-1} F'(x)^* \rangle^{-1} F(x), F(x) \right) \right]. \]

\[ \square \]

Note that the one-dimensional optimization problem in (5.8) can be solved efficiently by a standard technique developed for modern trust-region methods (see [1], Chapter 7).

Finally, let us mention that in Euclidean case our step strategy (5.9) can be seen as a variant of Levenberg-Marquardt method with a special rule for the choice of the proximal parameter \( \lambda^* \). In non-Euclidean case, the corresponding strategy could be also interpreted as a variant of the trust-region approach. However, the main advantage of our approach is that it is fully automatic. Moreover, it has unambiguous interpretation, which is crucial for justifying the global and local properties of the process (3.1).
