A reduced model for domain walls in soft ferromagnetic films at the cross-over from symmetric to asymmetric wall types.

Lukas Döring∗ Radu Ignat† Felix Otto∗

September 4, 2013

Abstract

We study the Landau-Lifshitz model for the energy of multi-scale transition layers – called “domain walls” – in soft ferromagnetic films. Domain walls separate domains of constant magnetization vectors $m^\pm \alpha \in S^2$ that differ by an angle $2\alpha$. Assuming translation invariance tangential to the wall, our main result is the rigorous derivation of a reduced model for the energy of the optimal transition layer, which in a certain parameter regime confirms the experimental, numerical and physical predictions: The minimal energy splits into a contribution from an asymmetric, divergence-free core which performs a partial rotation in $S^2$ by an angle $2\theta$, and a contribution from two symmetric, logarithmically decaying tails, each of which completes the rotation from angle $\theta$ to $\alpha$ in $S^1$. The angle $\theta$ is chosen such that the total energy is minimal. The contribution from the symmetric tails is known explicitly, while the contribution from the asymmetric core is analyzed in [7].

Our reduced model is the starting point for the analysis of a bifurcation phenomenon from symmetric to asymmetric domain walls. Moreover, it allows for capturing asymmetric domain walls including their extended tails (which were previously inaccessible to brute-force numerical simulation).

Keywords: $\Gamma$-convergence, concentration-compactness, transition layer, bifurcation, micromagnetics.

1 Introduction

1.1 Model

We consider the following model: The magnetization is described by a unit-length vector field
\[ m = (m_1, m_2, m_3): \Omega \to S^2, \]
where the two-dimensional domain
\[ \Omega = \mathbb{R} \times (-1, 1) \]
corresponds to a cross-section of the sample that is parallel to the \( x_1 x_3 \)-plane. The following “boundary conditions at \( x_1 = \pm \infty \)” are imposed so that a transition from the angle \( -\alpha \) to \( \alpha \in (0, \frac{\pi}{2}] \) is generated and a domain wall forms parallel to the \( x_2 x_3 \)-plane (see Figure 1):
\[ m(\pm \infty, \cdot) = m^\pm_\alpha := (\cos \alpha, \pm \sin \alpha, 0), \tag{1} \]
with the convention:
\[ f(\pm \infty, \cdot) = a_\pm \iff \int_{\Omega_+} |f - a_+|^2 \, dx + \int_{\Omega_-} |f - a_-|^2 \, dx < \infty, \tag{2} \]
where \( \Omega_+ = \Omega \cap \{ x_1 \geq 0 \} \) and \( \Omega_- = \Omega \cap \{ x_1 \leq 0 \} \). Throughout the paper, we use the variables \( x = (x_1, x_3) \in \Omega \) together with the differential operator \( \nabla = (\partial_{x_1}, \partial_{x_3}) \), and we denote by \( m' = (m_1, m_3) \) the projection of \( m \) on the \( x_1 x_3 \)-plane.

![Figure 1: The cross-section \( \Omega \) in a ferromagnetic sample on a mesoscopic level.](image)

We focus on the following micromagnetic energy functional depending on a small parameter \( \eta \):\(^1\)
\[ E_\eta(m) = \int_{\Omega} |\nabla m|^2 \, dx + \lambda \ln \frac{1}{\eta} \int_{\mathbb{R}^2} |h(m)|^2 \, dx + \eta \int_{\Omega} (m_1 - \cos \alpha)^2 + m_3^2 \, dx, \quad \eta \in (0, 1), \tag{3} \]
subject to the boundary conditions (1), where \( \lambda > 0 \) is a fixed constant and \( h = h(m): \mathbb{R}^2 \to \mathbb{R}^2 \) stands for the unique \( L^2 \) stray-field restricted to the \( x_1 x_3 \)-plane that is generated by the

\(^1\)We refer to Section 2 for more information on \( E_\eta \) and the parameters \( \eta \) and \( \lambda \).
static Maxwell equations:

\[
\begin{aligned}
\nabla \cdot (h + m' \mathbf{1}_\Omega) &= 0 \quad \text{in } \mathcal{D}'(\mathbb{R}^2), \\
\nabla \times h &= 0 \quad \text{in } \mathcal{D}'(\mathbb{R}^2).
\end{aligned}
\]

The first term of (3) is called the "exchange energy", favoring a constant magnetization. The second term (called "stray-field energy") can be written as the \(H^{-1}(\mathbb{R}^2)\)-norm of the 2D divergence of \(m'\) (where \(m\) is always extended by 0 outside of \(\Omega\)):

\[
\int_{\mathbb{R}^2} |h(m)|^2 dx = \|\nabla (m'1_\Omega)\|_{H^{-1}(\mathbb{R}^2)}^2 := \sup \left\{ \int_\Omega m' \cdot \nabla v dx \Bigg| v \in C^\infty_c(\mathbb{R}^2), \|\nabla v\|_{L^2(\mathbb{R}^2)} \leq 1 \right\}.
\]

The last term in (3) (a combination of material anisotropy and external magnetic field) forces the magnetization to favor the "easy axis" \(m_0\) and serves as confining mechanism for the tails of the transition layer. We refer to Section 2 for more physical details about this model.

We are interested in the asymptotic behavior of minimizers \(m_\eta\) of \(E_\eta\) with the boundary condition (1) as \(\eta \downarrow 0\). The main feature of this variational principle is the non-convex constraint on the magnetization (\(|m_\eta| = 1\)) and the non-local structure of the energy (due to the stray field \(h(m_\eta)\)). The competition between the three terms of the energy together with the boundary constraint (1) induces an optimal transition layer that exhibits two length scales (cf. Figure 3):

- an asymmetric core of size \((|x_1| \lesssim 1)\) (up to a logarithmic scale in \(\eta\)) where the magnetization \(m_\eta\) is asymptotically divergence-free (so, generating no stray field) and hence the leading order term in \(E_\eta\) is given by the exchange energy; in this region, \(m_\eta\) describes a transition path on \(S^2\) between the two directions \(m_\eta^\pm\) determined by some angle \(\theta\).
- two symmetric tails of size \((1 \lesssim |x_1| \lesssim \frac{1}{\eta})\) (up to a logarithmic scale in \(\eta\)) where \(m_\eta\) asymptotically behaves as a symmetric Néel wall: a one-dimensional (i.e., \(m_\eta = m_\eta(x_1)\)) rotation on \(S^1 := S^1 \times \{0\} \subset S^2\) between the angles \(\theta\) and \(\alpha\) (on the left and right sides of the core). Here, the formation of the wall profile is driven by the stray-field energy that induces a logarithmic decay of \(m_{1,\eta}\) on these two tails.

The constant \(\lambda > 0\) and the wall angle \(\alpha\) play a crucial role in the behavior of a minimizer \(m_\eta\). In fact, for either \(\alpha \ll 1\), or \(\alpha \in (0, \frac{\pi}{2})\) arbitrary but \(\lambda\) small, a minimizer is expected to be asymptotically symmetric (i.e., \(m_\eta = m_\eta(x_1)\)) as \(\eta \downarrow 0\). However, for sufficiently large \(\lambda\), there exists a critical wall angle \(\alpha^*\) where a bifurcation occurs: It becomes favorable to nucleate an asymmetric domain wall in the core of the transition layer.

In [10, Section 3.6.4 (E)], Hubert and Schäfer state:

\footnote{Existence and uniqueness of the stray field are a direct consequence of the Riesz representation theorem in the Hilbert space \(V = \left\{ v \in L^2_{\text{loc}}(\mathbb{R}^2) \, | \, \nabla v \in L^2, \int_{B(0,1)} \nabla v \cdot dx = 0 \right\}\) endowed with the norm \(\|\nabla v\|_{L^2}\). Indeed, by (1), the functional \(v \mapsto \int_{\Omega} (m' - (\cos \alpha, 0)) \cdot \nabla v \cdot dx\) is linear continuous on \(V\) so that there exists a unique solution \(h = -\nabla u\) with \(u \in V\) of (4) written in the weak form \(\int_{\mathbb{R}^2} \nabla u \cdot \nabla v \cdot dx = \int_{\Omega} m' \cdot \nabla v \cdot dx\) for every \(v \in C^\infty_c(\mathbb{R}^2)\).}
"The magnetization of an asymmetric Néel wall points in the same direction at both surfaces, which is [...] favourable for an applied field along this direction. This property is also the reason why the wall can gain some energy by splitting off an extended tail, reducing the core energy in the field generated by the tail. [...] The tail part of the wall profile increases in relative importance with an applied field, so that less of the vortex structure becomes visible with decreasing wall angle. At a critical value of the applied field the asymmetric disappears in favour of a symmetric Néel wall structure."

To justify this physical prediction, we will establish the asymptotic behavior of \( \{E_\eta\}_{\eta \downarrow 0} \) through the method of \( \Gamma \)-convergence. The limiting reduced model does then show that the minimal energy splits into the separate contributions from the symmetric and asymmetric regions of the transition layer. This makes it possible to infer information on the size of the regions and the conjectured bifurcation from symmetric to asymmetric walls. For details, we refer to Section 1.3.

### 1.2 Results

Let \( \alpha \in (0, \frac{\pi}{2}] \) and \( \eta \in (0, 1) \). Observe that for \( m: \Omega \to S^2 \), finite energy \( E_\eta(m) < \infty \) is equivalent to \( m \in \dot{H}^1(\Omega, S^2) \) and \( m'(\pm \infty, \cdot) \overset{(2)}{=} (\cos \alpha, 0) \) (which in particular implies \( |m_2(\pm \infty, \cdot)| = \sin \alpha \), see Lemma 3). In the following we focus on the set of magnetizations of wall angle \( \alpha \in (0, \frac{\pi}{2}] \) with a transition imposed by (1):

\[
X^\alpha := \left\{ m \in \dot{H}^1(\Omega, S^2) \mid m(\pm \infty, \cdot) = m^\pm_\alpha \right\}.
\] (5)

Our main result consists in proving \( \Gamma \)-convergence of \( \{E_\eta\}_{\eta \downarrow 0} \), defined on \( X^\alpha \subset \dot{H}^1(\Omega, S^2) \), in the weak \( \dot{H}^1 \)-topology to the \( \Gamma \)-limit functional

\[
E_0(m) = \int_\Omega |\nabla m|^2 dx + 2\pi \lambda (\cos \theta_m - \cos \alpha)^2,
\] (6)

which is defined on a space \( X_0 \subset \dot{H}^1(\Omega, S^2) \):

In order to give the definitions of \( X_0 \) (see (8)) and the angle \( \theta_m \) associated to \( m \in X_0 \) (see (7)), we need some preliminary remarks. First, due to the logarithmic penalization of the stray field in (3) as \( \eta \downarrow 0 \), limiting configurations of a family \( \{m_\eta\}_{\eta \downarrow 0} \) of uniformly bounded energy \( E_\eta(m_\eta) \leq C \) (e.g., minimizers of \( E_\eta \)) are stray-field free. Second, note that for any \( m \in \dot{H}^1(\Omega, S^2) \) with \( \nabla \cdot (m'1_\Omega) = 0 \) in \( \mathcal{D}'(\mathbb{R}^2) \) (i.e., \( \nabla \cdot m' = 0 \) in \( \Omega \) and \( m_3 = 0 \) on \( \partial \Omega \)) there is a unique constant angle \( \theta_m \in [0, \pi] \) such that

\[
\bar{m}_1(x_1) := \int_{-1}^{1} m_1(x_1, x_3) \, dx_3 = \cos \theta_m \quad \text{for all} \quad x_1 \in \mathbb{R}.
\] (7)

Observe that such vector fields have the property \( m'(\pm \infty, \cdot) = (\cos \theta_m, 0) \) in the sense of (2) (see (30) and (31) below) and moreover, \( |m_2(\pm \infty, \cdot)| = \sin \theta_m \) (see Lemma 3 if \( \theta_m \in (0, \pi) \), and Remark 1 below if \( \theta_m \in \{0, \pi\} \)). We define \( X_0 \) as the non-empty (see
Lemma 1. Let \( \pm \infty \) related to the change of sign at \( \theta_m \) in the sense of (2):

\[
X_0 := \left\{ m \in H^1(\Omega, \mathbb{S}^2) \mid \nabla \cdot m' = 0 \text{ in } \Omega, \ m_3 = 0 \text{ on } \partial \Omega, \ m(\pm \infty, \cdot) = m_{\mp} \right\}.
\] (8)

Note, however, that due to vanishing control of the anisotropy energy as \( \eta \downarrow 0 \), a limiting configuration \( m \) in general satisfies (1) for an angle \( \theta_m \) that differs from \( \alpha \).

Remark 1. Observe that if \( \theta_m \in \{0, \pi\} \) for \( m \in H^1(\Omega, \mathbb{S}^2) \) with \( \nabla \cdot (m(1_\Omega)) = 0 \) in \( \mathcal{D}'(\mathbb{R}^2) \) – in particular if \( m \in X_0 \) – we have \( m \in \{ \pm e_1 \} \): Indeed, since \( |\bar{m}| = 1 \) in \( \mathbb{R} \) and \( |m| = 1 \) in \( \Omega \), we deduce \( |m_1| = 1 \) and \( m_2 = m_3 = 0 \) in \( \Omega \).

We further remark that the first term in the \( \Gamma \)-limit energy (6) accounts for the exchange energy of the asymmetric core of a transition layer \( m_\eta \) as \( \eta \downarrow 0 \), while the second term in \( E_0 \) accounts for the contribution coming from stray field/anisotropy energy through extended (symmetric) tails of the wall configurations at positive \( \eta \).

Our \( \Gamma \)-convergence result is established in three steps. We start with compactness results. The main difficulty comes from the boundary conditions (1), which are in general not carried over by weak limits of magnetization configurations with uniformly bounded exchange energy. However, since the energy \( E_\eta \) is invariant under translations in \( x_1 \)-direction, and due to the constraint (1) in \( X^\alpha \), a change of sign in \( m_2 \) can be preserved as \( \eta \downarrow 0 \) by a suitable translation in \( x_1 \).

Proposition 1 (Compactness). Let \( \alpha \in (0, \frac{\pi}{2}] \). The following convergence results hold up to a subsequence and translations in the \( x_1 \)-variable:

(i) Let \( \{m_\eta\}_{\eta \downarrow 0} \subset X^\alpha \) with uniformly bounded energy, i.e., \( \sup_{\eta \downarrow 0} E_\eta(m_\eta) < \infty \). Then \( m_\eta \rightharpoonup m \) weakly in \( H^1(\Omega) \) for some \( m \in X_0 \).

(ii) Let \( \{m_k\}_{k \uparrow \infty} \subset X^\alpha \) with uniformly bounded energy \( E_\eta \) for \( \eta \in (0, 1) \) fixed, i.e., \( \sup_k E_\eta(m_k) < \infty \). Then \( m_k \rightharpoonup m \) weakly in \( H^1(\Omega) \) for some \( m \in X^\alpha \). Moreover, the corresponding stray fields \( \{\nabla m_k\}_{k \uparrow \infty} \) converge weakly in \( L^2(\mathbb{R}^2) \), i.e., \( \nabla m_k \rightharpoonup \nabla m \) in \( L^2(\mathbb{R}^2) \).

(iii) Let \( \{m_k\}_{k \uparrow \infty} \subset X_0 \) with uniformly bounded exchange energy, i.e., \( \sup_k \int_\Omega |\nabla m_k|^2 \, dx < \infty \), such that the angles \( \theta_k := \theta_{m_k} \) associated to \( m_k \) in (7) satisfy \( \theta_k \in [0, \pi] \). Then \( \theta_k \to \theta \) for some angle \( \theta \in [0, \pi] \) and \( m_k \rightharpoonup m \) weakly in \( H^1(\Omega) \) for some \( m \in X_0 \) with \( \theta_m = \theta \) (i.e., \( m \in X_0 \cap X^\theta \)).

The main ingredient in Proposition 1 is the following concentration-compactness type lemma related to the change of sign at \( \pm \infty \):

Lemma 1. Let \( u_k : \mathbb{R} \to \mathbb{R}, k \in \mathbb{N}, \) be continuous and satisfy the following conditions:

\[
\limsup_{k \uparrow \infty} \int_{\mathbb{R}} \left| \frac{d}{ds} u_k(s) \right|^2 ds < \infty,
\] (9)

\[
\limsup_{s \downarrow -\infty} u_k(s) < 0 \text{ and } \liminf_{s \uparrow \infty} u_k(s) > 0 \text{ for every } k \in \mathbb{N},
\] (10)
where we denote by $\frac{d}{ds} u_k$ the distributional derivative of the function $u_k$.

Then for each $k \in \mathbb{N}$, there exists a zero $z_k$ of $u_k$ and a limit $u \in \dot{H}^1(\mathbb{R})$ such that $u(0) = 0$,

$$u_k(\cdot + z_k) \to u \text{ locally uniformly in } \mathbb{R} \text{ and weakly in } \dot{H}^1(\mathbb{R}) \text{ for a subsequence}$$

and

$$\limsup_{s \to -\infty} u(s) \leq 0 \quad \text{as well as} \quad \liminf_{s \to \infty} u(s) \geq 0. \quad (11)$$

The second step consists in proving the following lower bound:

**Theorem 1** (Lower bound). Let $\alpha \in \left(0, \frac{\pi}{2}\right]$. For $m \in X_0$ and any family $\{m_\eta\}_{\eta \downarrow 0} \subset X^\alpha$ with $m_\eta \to m$ in $\dot{H}^1(\Omega)$ as $\eta \downarrow 0$, the following lower bound holds:

$$\liminf_{\eta \downarrow 0} E_\eta(m_\eta) \geq E_0(m). \quad (12)$$

The last step consists in constructing recovery sequences for limiting configurations:

**Theorem 2** (Upper bound). For $\alpha \in \left(0, \frac{\pi}{2}\right]$ and every $m \in X_0$ there exists a family $\{m_\eta\}_{\eta \downarrow 0} \subset X^\alpha$ with $m_\eta \to m$ strongly in $\dot{H}^1(\Omega)$ and

$$\limsup_{\eta \downarrow 0} E_\eta(m_\eta) \leq E_0(m). \quad (13)$$

As a consequence, one deduces the asymptotic behavior of the minimal energy $E_\eta$ over the space $X^\alpha$ as $\eta \downarrow 0$.

**Corollary 1.** For $\alpha \in \left(0, \frac{\pi}{2}\right]$ and $\theta \in [0, \pi]$ we define

$$E_{\text{asym}}(\theta) = \min_{m \in X_0} \int_\Omega |\nabla m|^2 dx$$

and

$$E_{\text{sym}}(\alpha - \theta) = 2\pi (\cos \theta - \cos \alpha)^2.$$

Then it holds

$$\lim_{\eta \downarrow 0} \min_{m_\eta \in X^\alpha} E_\eta(m_\eta) = \min_{m \in X_0} E_0(m) = \min_{\theta \in [0, \pi]} \left( E_{\text{asym}}(\theta) + \lambda E_{\text{sym}}(\alpha - \theta) \right). \quad (14)$$

In fact, the optimal angle $\theta$ is attained in $[0, \frac{\pi}{2}]$. Moreover, every minimizing sequence $\{m_\eta\}_{\eta \downarrow 0} \subset X^\alpha$ of $\{E_\eta\}_{\eta \downarrow 0}$ in the sense of $E_\eta(m_\eta) \to \min_{X_0} E_0$ is relatively compact in the strong $\dot{H}^1(\Omega)$-topology, up to translations in $x_1$, having as accumulation points in $X_0$ minimizers of $E_0$.

One benefit of (14) is splitting the problem of determining the optimal transition layer into two more feasible ones: First, the energy of asymmetric walls (i.e. walls of small width) has to be determined (at the expense of an additional constraint on $\nabla \cdot m'$). Afterwards, a one-dimensional minimization procedure is sufficient to determine the structure of the wall profile. Direct numerical simulation of (3) has been a difficult endeavor (see [17] and also [10, Section 3.6.4 (E)]).
1.3 Outlook

In the following we briefly discuss an application of our reduced model to the cross-over from symmetric to asymmetric Néel wall and point out further interesting (topological) questions and open problems associated with the energy of asymmetric domain walls.

**Bifurcation.** The previous result represents the starting point in the analysis of the bifurcation phenomenon (from symmetric to asymmetric walls) in terms of the wall angle \( \alpha \) (see also [7]). We will prove that there is a supercritical (pitchfork) bifurcation (cf. Figure 2): This means that for small angles \( \alpha \ll 1 \), the optimal transition layer \( m_\eta \) of \( E_\eta \) is asymptotically symmetric (the symmetric Néel wall); beyond a critical angle \( \alpha^* \), the symmetric wall is no longer stable, whereas the asymmetric wall is. To understand the type of the bifurcation, by (14), we need to compute the asymptotic expansion of the asymmetric energy up to order \( \theta^4 \) as \( \theta \to 0 \) (since the symmetric part of the energy is quartic for small angles \( \theta, \alpha \ll 1 \), i.e., \( E_{\text{asym}}(\alpha - \theta) \lesssim \alpha^4 \)).

In fact, we show (see [7]):

\[
E_{\text{asym}}(\theta) = 4\pi\theta^2 + \frac{304}{105}\pi\theta^4 + o(\theta^4) \quad \text{as} \quad \theta \downarrow 0.
\] (15)

This allows us to heuristically determine a critical angle \( \alpha^* \) at which the symmetric Néel wall loses stability and an asymmetric core is generated. Moreover, a new path of stable critical points with increasing inner wall angle \( \theta \) branches off of \( \theta = 0 \) (see Figure 2). Indeed, for small \( \alpha \), combining with (15), the RHS of (14) as function of \( \theta \in [0, \alpha] \) has the unique critical point \( \theta = 0 \) if \( \alpha \leq \alpha^* \) where the bifurcation angle \( \alpha^* \) is given by

\[
\alpha^* = \arccos \left( 1 - \frac{2}{3} \right) + o(1), \quad \text{as} \quad \alpha \to 0.
\]

(Observe that \( \alpha^* \in [0, \frac{\pi}{2}] \) provided \( \lambda \geq 2 \); therefore, the bifurcation appears only if \( \lambda \) is large enough.) For \( \alpha > \alpha^* \), the symmetric wall becomes unstable under symmetry-breaking perturbations and the optimal splitting angle \( \theta \) becomes positive; hence, the asymmetric wall becomes favored by the system. Moreover, the second variation of the RHS of (14) along the branch of positive splitting angles is positive so that the bifurcation from symmetric to asymmetric wall is supercritical.

**Topological degree and vortex singularity.** We now discuss topological properties of stray-field free magnetization configurations: In fact, if \( m \in X_0 \) satisfies (1) for some angle \( \theta \in (0, \frac{\pi}{2}] \), denoting the “extended” boundary of \( \Omega \)

\[
\overline{Bdry} := \partial \Omega \cup \left\{ \{-\infty\} \times [-1, 1] \right\} \cong S^1,
\] (16)

then one can define the following winding number of \( m \) on \( \overline{Bdry} \): due to \( m_3 = 0 \) on \( \partial \Omega \) as well as \( m_3(\pm\infty, \cdot) = 0 \) (so, \( (m_1, m_2): \overline{Bdry} \to S^1 \)), one obtains (by the homeomorphism (16)) a map \( \tilde{m} \in H^1(S^1, S^1) \) to which a topological degree can be associated (see, e.g., [4]).

\(^3\)Observe that for given \( \alpha \in (0, \frac{\pi}{2}] \) the optimal wall angle \( \theta_\alpha = \arg\min \left( E_{\text{asym}}(\theta) + \lambda E_{\text{sym}}(\alpha - \theta) \right) \in [0, \frac{\pi}{2}] \) satisfies the estimate \( \theta_\alpha \lesssim \alpha^2 \). Indeed, by comparison with \( \theta = 0 \) we have \( E_{\text{asym}}(\theta_\alpha) + 2\pi \lambda (\cos \theta_\alpha - \cos \alpha)^2 \lesssim 2\pi \lambda (1 - \cos \alpha)^2 \). Omitting \( E_{\text{asym}}(\theta_\alpha) \) we first obtain \( \theta_\alpha \to 0 \) as \( \alpha \downarrow 0 \), so that by (15) one deduces that \( 2\theta_\alpha^2 \lesssim \lambda (1 - \cos \alpha)^2 \) for small \( \alpha > 0 \). From here, the desired estimate follows.
In particular, in the case of smooth $\tilde{m} : S^1 \to S^1$, the topological degree (also called winding number) of $\tilde{m}$ is defined as follows:

$$\deg(\tilde{m}) := \frac{1}{2\pi} \int_{S^1} \det(\tilde{m}, \partial_\theta \tilde{m}) dH^1$$

where $\partial_\theta \tilde{m}$ is the angular derivative of $\tilde{m}$.

We will show the following relation between the winding number of $m \in X_0$ on $\overline{\text{Bdry}}$ and topological singularities of $(m_1, m_3)$ inside $\Omega$: the non-vanishing topological degree of $(m_1, m_3) : \overline{\text{Bdry}} \to S^1$ generates vortex singularities of $(m_1, m_3)$ as illustrated in Figure 3. By vortex singularity of $v := (m_1, m_3)$, we understand a zero of $v$ carrying a non-zero topological degree. In general, this is implied by the existence of a smooth cycle (i.e., closed curve) $\gamma \subset \Omega$ such that $|v| > 0$ on $\gamma$ and $\deg(v, \gamma) \neq 0$; the vector field $v$ then vanishes in the domain bounded by $\gamma$.

**Lemma 2.** Let $m \in X_0$ (i.e. $m \in \dot{H}^1(\Omega, S^2)$ with $\nabla \cdot (m' 1_{\Omega}) = 0$ in $\mathcal{D}'(\mathbb{R}^2)$) such that (1) holds for some angle $\theta \in (0, \pi/2]$. Suppose that $(m_1, m_2) : \overline{\text{Bdry}} \to S^1$ has a non-zero winding number on $\overline{\text{Bdry}}$. Then there exists a vortex singularity of $(m_1, m_3)$ in $\Omega$ carrying a non-zero topological degree.

Motivated by Lemma 2, let us introduce the set

$$\mathcal{L}^\theta = \{ m \in X_0 \cap X^\theta : \deg m = 1 \}$$

for a fixed angle $\theta \in (0, \pi/2]$. First of all, we have that $\mathcal{L}^\theta \neq \emptyset$ (see Appendix).

Since $X_0 = \cup_{\theta \in [0, \pi]} (X_0 \cap X^\theta)$, the relation $\mathcal{L}^\theta \neq \emptyset$ obviously implies that $X_0 \cap X^\theta \neq \emptyset$ for every $\theta \in (0, \pi)$ which is essential in our reduced model given by the $\Gamma$-convergence program. A natural question concerns the closure (in the weak $\dot{H}^1(\Omega)$-topology) of the set $\mathcal{L}^\theta$. This is

 Naturally, one can address a similar question by imposing an arbitrary winding number $n$. For the case $n = 0$, we analyze this problem in [7] which is typical for asymmetric Néel walls; in particular, for small angles $\theta$, we construct an element $m \in X_0 \cap X^\theta$ with deg $m = 0$ and asymptotically minimal energy. Moreover, given any $m \in X_0 \cap X^\theta$ with finite energy, one can use a reflection and rescaling argument to define a finite-energy magnetization on $\Omega$ with degree 0 (see Remark 5 (iii)).
important in order to define the (limit) asymmetric Bloch wall by minimizing the exchange 
energy on $L^\theta$. 5

**Open problem 1.** *Is the following infimum*

$$\inf_{m \in L^\theta} \int_\Omega |\nabla m|^2 \, dx$$

*attained for every angle $\theta \in (0, \frac{\pi}{2}]$?*

### 1.4 Structure of the paper

This paper is organized as follows: In Section 2, we explain the relation of (3) to the full 
Landau-Lifshitz energy, as well as the physical background of our analysis.

In Section 3, we prove the compactness results in Lemma 1 and Proposition 1, which in 
perticular yield existence of minimizers of $E_\eta$, $E_{\text{asym}}(\theta)$ and $E_0$.

Section 4 contains the proofs of the lower and upper bound (Theorems 1 and 2) of our 
$\Gamma$-convergence result and also, the proof of Corollary 1.

In the Appendix, finally, we show that the set $X_0 \cap X^\theta$ is non-empty for any given angle 
$\theta \in (0, \frac{\pi}{2}]$. To this end, we construct an admissible configuration in $E_{\text{asym}}(\theta)$ with non-zero 
topological degree on the boundary of $\Omega$ (i.e., of asymmetric Bloch-wall type). Moreover, we 
prove Lemma 2.

### 2 Physical background

In this section, we denote by $\nabla = (\partial_{x_1}, \partial_{x_2}, \partial_{x_3})$ the full gradient of functions depending 
on $x = (x_1, x_2, x_3)$. Recall that the prime $'$ denotes the projection on the $x_1x_3$-plane, i.e. 
$\nabla' = (\partial_{x_1}, \partial_{x_3})$, $x' = (x_1, x_3)$.

**Micromagnetics.** Let $\omega \subset \mathbb{R}^3$ represent a ferromagnetic sample whose magnetization is 
described by the unit-length vector-field $m: \omega \to S^2$. Assume that the sample exhibits 
a uniaxial anisotropy with $e_2 = (0, 1, 0)$ as "easy axis", i.e. favored direction of $m$. The 
well-accepted micromagnetic model (see e.g. [5, 10]) states that in its ground state the 
magnetization minimizes the Landau-Lifshitz energy:

$$E^{3D}(m) = d^2 \int_\omega |\nabla m|^2 \, dx + \int_{\mathbb{R}^3} |h(m)|^2 \, dx + Q \int_\omega m_1^2 + m_2^2 \, dx - 2 \int_\omega h_{\text{ext}} \cdot m \, dx.$$  (17)

Here, the exchange length $d$ is a material parameter that determines the strength of the 
exchange interaction of quantum mechanical origin, relative to the strength of the stray field 
h = $h(m)$. The stray field is the gradient field $h = -\nabla u$ that is (uniquely) generated by the 
distributional divergence $\nabla \cdot (m 1_\omega)$ via Maxwell’s equation

$$\nabla \cdot (h + m 1_\omega) = 0 \quad \text{in } D'(\mathbb{R}^3).$$  (18)

5This question is related to the theory of Ginzburg-Landau minimizers with prescribed degree (see e.g. 
Berlyand and Mironescu [2]).
The non-dimensional quality factor $Q > 0$ is a material constant that measures the relative strength of the energy contribution coming from misalignment of $m$ with $e_2$. The last term, called Zeeman energy, favors alignment of $m$ with an external magnetic field $h_{\text{ext}}: \omega \rightarrow \mathbb{R}^3$.

**Derivation of our model.** We assume the magnetic sample to be a thin film, infinitely extended in the $(x_1, x_2)$-plane, i.e. $\omega = \mathbb{R}^2 \times (-t, t)$, where two magnetic domains of almost constant magnetization $m \approx m_{\text{core}}^{\pm}$ have formed for $\pm x_1 \gg t$. Physically, such a configuration is stabilized by the combination of uniaxial anisotropy and suitably chosen external field $h_{\text{ext}} = Q \cos \alpha e_1$. Moreover, we assume that $m$ and hence, the stray field $h = (h_1, 0, h_3)$ are independent of the $x_2$-variable so that (17) formally reduces to integrating the energy density (per unit length in $x_2$-direction):

$$E^{2D}(m) = d^2 \int_{\omega'} |\nabla' m|^2 dx' + \int_{\mathbb{R}^2} |h'|^2 dx' + Q \int_{\omega'} (m_1 - \cos \alpha)^2 + m_2^2 dx'$$

where $\omega' = \mathbb{R} \times (-t, t)$ and $h' = h'(m) = -\nabla' u$ satisfies (4) driven by the 2D divergence of $m' 1_{\omega'}$. Recall that the prime $'$ here denotes a projection onto the coordinate directions $(x_1, x_3)$ transversal to the wall plane. After non-dimensionalization of length with the film thickness $t$, i.e., setting $\tilde{x}' = \frac{x'}{t}$, $\tilde{x}'' = \frac{x''}{t}$, $\tilde{m}(\tilde{x}') = m(x')$, $\tilde{u}(\tilde{x}') = \frac{u(x')}{t}$, the above specific energy (per unit length in $x_2$) is given by

$$\tilde{E}^{2D}(\tilde{m}) = d^2 \int_{\tilde{\omega}'} |\tilde{\nabla}' \tilde{m}|^2 d\tilde{x}' + t^2 \int_{\mathbb{R}^2} |\tilde{\nabla}' \tilde{u}|^2 d\tilde{x}' + Qt^2 \int_{\tilde{\omega}'} (\tilde{m}_1 - \cos \alpha)^2 + \tilde{m}_2^2 d\tilde{x}', \quad (19)$$

where the differential operator $\tilde{\nabla}'$ refers to the variables $\tilde{x}' = (\tilde{x}_1, \tilde{x}_3)$ and $\tilde{u}: \mathbb{R}^2 \rightarrow \mathbb{R}$ is the 2D stray-field potential given by

$$\tilde{\Delta}' \tilde{u} = \tilde{\nabla}' \cdot (\tilde{m} 1_{\tilde{\omega}'}) \text{ in } D'(\mathbb{R}^2).$$

Throughout the section, we omit $^-$ and $'$.

**Symmetric walls.** In the regime of very thin films (i.e. for a sufficiently small ratio of film thickness $t$ to exchange length $d$, see below for the precise regime), the symmetric Néel wall $m$ is the favorable transition layer: It is characterized by a reflection symmetry w.r.t. the midplane $x_3 = 0$, see 3) below. In fact, to leading order in $\frac{t}{d}$, it is independent of the thickness variable $x_3$, i.e. $m = m(x_1)$, and in-plane, i.e. $m_3 = 0$. The symmetric Néel wall is a two length-scale object with a core of size $w_{\text{core}} = O(\frac{d}{Q})$ and two logarithmically decaying tails $w_{\text{core}} \lesssim |x_1| \lesssim w_{\text{tail}} = O(\frac{1}{Q})$ (see e.g. Melcher [15, 16]). It is invariant w.r.t. all the symmetries of the variational problem (besides translation invariance):

1) $x_1 \rightarrow -x_1, x_3 \rightarrow -x_3, m_2 \rightarrow -m_2$;
2) $x_1 \rightarrow -x_1, m_3 \rightarrow -m_3, m_2 \rightarrow -m_2$;
3) $x_3 \rightarrow -x_3, m_3 \rightarrow -m_3$;
4) $Id$.

A typical, experimentally accessible, soft ferromagnetic material is Permalloy, for which $d \approx 5 \text{nm}$ and $Q = 2.5 \cdot 10^{-4}$.
The specific energy of a Néel wall of angle $\alpha = \frac{\pi}{2}$ is given by

$$E^{2D}(\text{symmetric Néel wall}) = O(t^2 \frac{1}{\ln \frac{w_{\text{tail}}}{w_{\text{core}}}}) = O(t^2 \frac{1}{\ln \frac{t^2}{d^2Q}})$$

(see e.g. [19, 5]). For a symmetric Néel wall of angle $\alpha < \frac{\pi}{2}$, the energy is asymptotically quartic in $\alpha$ as it is proportional to $(1 - \cos \alpha)^2$ (see e.g. [11]).

**Asymmetric walls.** For thicker films, the optimal transition layer has an asymmetric core, where the symmetry 3) is broken (see e.g. [8, 9]). The main feature of this asymmetric core is that it is approximately stray-field free. Hence to leading order, the asymmetric core is given by a smooth transition layer $m$ that satisfies (1) and

$$m: \omega \to S^2, \nabla \cdot m' = 0 \text{ in } \omega \text{ and } m_3 = 0 \text{ on } \partial \omega.$$

(20)

Observe that $(m_1, m_2): \partial \omega \to S^1$ since $m_3$ vanishes on $\partial \omega$, so that one can define a topological degree of $(m_1, m_2)$ on $\partial \omega$ (where $\partial \omega$ is the closed “infinite” curve $(\mathbb{R} \times \{\pm 1\}) \cup ((-\infty, -1] \times [1, \infty))$). The physical experiments, numerics and constructions predict two types of asymmetric walls, differing in their symmetries and the degree of $(m_1, m_2)$ on $\partial \omega$:

(i) For small wall angles $\alpha$, the system prefers the so-called asymmetric Néel wall. Its main features are the conservation of symmetries 1) and 4) and a vanishing degree of $(m_1, m_2)$ on $\partial \omega$ (see Figure 3). Due to symmetry 1), the $m_2$ component of an asymmetric Néel wall vanishes on a curve that is symmetric with respect to the center of the wall (by $x \rightarrow -x$). Moreover, the phase of $(m_1, m_2)$ is not monotone at the surface $|x_3| = 1$.

(ii) For large wall angles $\alpha$, the system prefers the so-called asymmetric Bloch wall. These walls only have the trivial symmetry 4). Another difference is the non-vanishing topological degree on $\partial \omega$ (i.e., $\deg((m_1, m_2), \partial \omega) = \pm 1$). Therefore, a vortex is nucleated in the wall core, and the curve of zeros of $m_2$ is no longer symmetric with respect to the center of the wall (see Figure 3). Moreover, the phase of $(m_1, m_2)$ is expected to be monotone at the surface $|x_3| = 1$.

The asymmetric wall has a single length scale $w_{\text{core}} \sim t$ and the specific energy comes from the exchange energy (see e.g. [19, 5]). It is of the order

$$E^{2D}(\text{asymmetric wall}) = O(d^2).$$

For small wall angles, the energy of the optimal asymmetric wall is asymptotically quadratic in $\alpha$ (see [5]).

**Regime.** We focus on the challenging regime of soft materials of thickness $t$ close to the exchange length $d$ (up to a logarithm), where we expect the cross-over in the energy scaling of symmetric walls and asymmetric walls (see [19]):

$$Q \ll 1 \text{ and } \ln \frac{t}{Q} \sim (\frac{t}{Q})^2.$$

Footnote: The magnetization was obtained by numerically solving the Euler-Lagrange equation corresponding to $E_{\text{Asym}}(\theta)$. To this end, a Newton method with suitable initial data was employed.
Rescaling the energy \( (19) \) by \( d^2 \) and setting
\[
\eta := Q\frac{t^2}{d^2} \ll 1 \quad \text{and} \quad \lambda := \frac{t^2}{d^2 \ln \eta} > 0,
\]
then \( \lambda = \mathcal{O}(1) \) is a tuning parameter in the system, and the rescaled energy, which is to be minimized, takes the form of energy \( E_\eta \) given in (3) under the constraint
\[
m: \Omega = \mathbb{R} \times (-1,1) \to S^2, \quad m(\pm\infty, \cdot) = m^\pm_\eta,
\]
\[
h = -\nabla u: \mathbb{R}^2 \to \mathbb{R}^2, \quad \nabla \cdot (h + m' 1_\Omega) = 0 \text{ in } D'(\mathbb{R}^2).
\]

Observe that the parameter \( \lambda \) measures the film thickness \( t \) relative to the film thickness \( d \ln \frac{1}{\eta} \) characteristic to the cross-over. The limit \( \eta \downarrow 0 \) corresponds to a limit of vanishing strength of anisotropy, while at the same time the relative film thickness \( \frac{t}{d} \) increases in order to remain in the critical regime of the cross-over.

**Other microstructures in micromagnetics.** In other asymptotic regimes, different pattern formation is observed. Let us briefly mention three other microstructures that were recently studied: the concertina pattern, the cross-tie wall and a zigzag pattern.

*Concertina pattern.* In a series of papers ([20, 23] among others) the formation and hysteresis of the concertina pattern in thin, sufficiently elongated ferromagnetic samples were studied. While in this case the transition layers between domains of constant magnetization are symmetric Néel walls, the program carried out for the concertina (a mixture of theoretical and numerical analysis, and comparison to experiments) serves as motivation for our work on the energy of domain walls in moderately thin films. Moreover, we hope that our analysis of the wall energy is helpful for studying a different route to the formation of the concertina pattern in not too elongated samples as proposed in [24], see also [6].

*Cross-tie wall.* An interesting transition layer observed in physical experiments is the cross-tie wall (see [10, Section 3.6.4]). It was rigorously studied in a reduced 2D model (by assuming vertical invariance of the magnetization) where a forcing term amounts to strong planar anisotropy that dominates the stray-field energy (see [1, 21, 22]). For small wall angles \( \theta \in (0, \frac{\pi}{4}] \), the optimal transition layer is given by the symmetric Néel wall; for larger angles...
ξ > \frac{\pi}{4}, the domain wall has a two-dimensional profile consisting in a mixture of vortices and Néel walls. The energetic cost of a transition in this 2D model is proportional to \( \sin \theta - \theta \cos \theta \), so it is cubic in \( \theta \) as \( \theta \to 0 \). This is due to the scaling of the stray-field energy (because of the thickness invariance assumption), which makes this reduced 2D model seem artificial. In the physics literature, it is known that for the full 3D model and large wall angles the cross-tie wall may also be favored over the asymmetric Bloch wall. We hope that our more realistic wall-energy density confirms and helps to quantify this issue.

A zigzag pattern. In thick films, zigzag walls also occur. This pattern has been studied by Moser [18] in a 3D model with a uniaxial anisotropy in an external magnetic field perpendicular to the “easy axis” (rather similar to our model). In fact, zigzag walls are to be expected there; however, this question is still open since the upper bound given for the limiting wall energy through a zigzag construction does not match the lower bound. Recently, in a reduced 2D model, Ignat and Moser [13] succeeded to rigorously prove the optimality of the zigzag pattern (for small wall angles). This was due to the improvement of the lower bound based on an entropy method (coming from scalar conservation laws). Remarkably, the function \( \sin \theta - \theta \cos \theta \) plays an important role for the limiting energy density in that context as well as for the cross-tie wall.

3 Compactness and existence of minimizers

In this section we prove compactness results for sequences \( \{m_k\}_{k \uparrow \infty} \) of magnetizations of bounded exchange energy. As an application we will derive existence of minimizers of \( E_\eta \) (for some fixed \( \eta \in (0, 1) \)) and \( E_{\text{asy}(\theta)} \) subject to a prescribed wall angle \( \theta \in (0, \pi) \), and show that the optimal angle in \( E_0 \) is attained (cf. (14)).

All these statements are rather straightforward up to one point: The condition of sign-change

\[ \pm m_2(\pm \infty, \cdot) \geq 0 \]

can in general not be recovered in the limit as shown in Figure 4.

![Figure 4: The x3-average \( \bar{m}_{2,\eta} \) of the m2-component. The arrow \( \longleftrightarrow \) denotes that the length of the corresponding interval grows to +\( \infty \) as \( \eta \downarrow 0 \). Then the limit \( \bar{m}_2 \) (as \( \eta \downarrow 0 \)) has the same sign at +\( \infty \) and -\( \infty \).](image)

However, we will show that one can always choose zeros \( x_{1,\eta} \) of \( \bar{m}_{2,\eta} \) in such a way that \( m_\eta(\cdot + x_{1,\eta}, \cdot) \) has the correct change of sign in the limit \( \eta \downarrow 0 \).
In the sequel we denote by $C > 0$ a universal, generic constant, whose value may change from line to line, unless otherwise stated.

### 3.1 Compactness

We start by proving the 1D concentration-compactness result stated in Lemma 1.

**Proof of Lemma 1:** Due to (10), the set $Z_k := \{ z \in \mathbb{R} \mid u_k(z) = 0 \}$ of zeros of $u_k$ is non-empty, and up to a translation in $x_1$-direction we may assume $u_k(0) = 0$ for all $k \in \mathbb{N}$.

**Step 1:** For every sequence $\{ z_k \in Z_k \}_{k \uparrow \infty}$ there exist a subsequence $\Lambda \subset \mathbb{N}$ and a limit $u : \mathbb{R} \to \mathbb{R}$ such that $u_k(\cdot + z_k) \to u$ locally uniformly for $k \uparrow \infty, k \in \Lambda$. Moreover, we have the bound

$$\int_{\mathbb{R}} |\frac{d}{ds} u_k|^2 ds \leq \liminf_{k \uparrow \infty} \int_{\mathbb{R}} |\frac{d}{ds} u_k|^2 ds < \infty.$$  

Indeed, by Cauchy-Schwarz’s inequality, we have for $t \neq \hat{t}$ that

$$\frac{|u_k(t) - u_k(\hat{t})|^2}{|t - \hat{t}|} = \frac{\left(\int_t^{\hat{t}} |\frac{d}{ds} u_k|^2 ds\right)^2}{|t - \hat{t}|} \leq \int_{\mathbb{R}} |\frac{d}{ds} u_k|^2 ds,$$

thus, by (9), we deduce that $\{ u_k(\cdot + z_k) \}_{k \uparrow \infty}$ is uniformly Hölder continuous with exponent $\frac{1}{2}$. In particular, since $u_k(z_k) = 0$, we also have that $\{ u_k(\cdot + z_k) \}_{k \uparrow \infty}$ are locally uniformly bounded. Hence, the Arzelà-Ascoli compactness theorem yields uniform convergence on each compact interval $[-n, n], n \in \mathbb{N}$, up to a subsequence. By a diagonal argument, one finds a subsequence $\Lambda \subset \mathbb{N}$ and a continuous limit $u : \mathbb{R} \to \mathbb{R}$ such that

$$u_k(\cdot + z_k) \to u \text{ locally uniformly for } k \uparrow \infty, k \in \Lambda.$$  

Moreover, the $L^2(\mathbb{R})$-estimate on $\frac{d}{ds} u$ follows from weak convergence in $L^2$ of $\frac{d}{ds} u_k$ and weak lower-semicontinuity of the $L^2$ norm.

**Step 2:** Inductive construction of zeros. Assume by contradiction that for every sequence $\{ z_k \in Z_k \}_{k \uparrow \infty}$, no accumulation point $u$ (w.r.t. to locally uniform convergence) of the sequence $\{ u_k(\cdot + z_k) \}_{k \uparrow \infty}$ satisfies (11). We will show by an iterative construction that one can select a subsequence of $\{ u_k \}_{k \uparrow \infty}$ such that each term $u_k$ has asymptotically infinitely many zeros (i.e., $\# Z_k \to \infty$ as $k \uparrow \infty$) with large distances in-between.

More precisely, we prove that for every $l \in \mathbb{N}$ there exist a limit $u' \in \dot{H}^1(\mathbb{R})$ and subsequences $\Lambda_l \subset \Lambda_{l-1} \subset \ldots \subset \Lambda_1 \subset \mathbb{N}$, such that for all $k \in \Lambda_l$ there exists an additional zero $z_k^l \in Z_k$ of $u_k$ with the properties:

$$\min_{1 \leq i \neq j \leq l} |z_k^i - z_k^j| \to \infty \quad \text{and} \quad u_k(\cdot + z_k^l) \to u' \text{ locally uniformly, as } k \uparrow \infty, k \in \Lambda_l.$$  

In Step 3, we finally show that this construction implies that $u \equiv 0$ is one of the accumulation points of $\{ u_k(\cdot + z_k) \}_{k \uparrow \infty}$ for $z_k \in Z_k$ a diagonal sequence of these $z_k^l$, i.e., (11) is satisfied, in contradiction to our assumption.
At level \( l = 1 \), we choose the zero \( z_k^1 = 0 \) of \( u_k \) for every \( k \in \mathbb{N} \). Then by Step 1, there exists a subsequence \( \Lambda_1 \subset \mathbb{N} \) and a limit \( u^1 \in H^1(\mathbb{R}) \) such that

\[
u_k(\cdot + z_k^1) \to u^1 \text{ locally uniformly for } k \uparrow \infty, \ k \in \Lambda_1.
\]

By assumption, \( u^1 \) does not satisfy (11). Hence, there exists \( \varepsilon_1 > 0 \) such that for every \( s > 0 \) we can find \( s_1 > s \) such that

\[
u^1(s_1) \leq -\varepsilon_1 < 0 \quad \text{or} \quad \nu^1(-s_1) \geq \varepsilon_1 > 0.
\]

By uniform convergence, we also deduce that for every \( s > 0 \) there exists an index \( k_s \in \Lambda_1 \) such that

\[
sup_{[-s_1,s_1]} |\nu_k(\cdot + z_k^1) - u^1| \leq \frac{s}{2} \quad \text{for } k \geq k_s, \ k \in \Lambda_1,
\]

which in particular implies that

\[
u_k(s_1 + z_k^1) < 0 \quad \text{or} \quad \nu_k(-s_1 + z_k^1) > 0, \quad \text{for } k \geq k_s, \ k \in \Lambda_1. \tag{21}
\]

At level \( l = 2 \), we proceed as follows: By the construction at level \( l = 1 \), for every \( s := n \in \mathbb{N} \) we choose as above \( s_1 \geq n \) and \( k := k_n \in \Lambda_1 \) (here, \( \{k_n\}_{n \uparrow \infty} \) is to be chosen increasing). We also know that \( u_k \) satisfies (11) which implies by (21) that \( u_k \) changes sign at the left of \( -s_1 + z_k^1 \) or at the right of \( s_1 + z_k^1 \). Choose \( z_k^2 \in Z_k \) as this new zero of \( u_k \). Since \( z_k^2 = 0 \), we have

\[|z_k^1 - z_k^2| \to \infty \text{ as } n \uparrow \infty.
\]

Let \( \tilde{\Lambda}_2 = \{k_n \mid n \in \mathbb{N}\} \subset \Lambda_1 \) be the sequence of these indices. By Step 1, there exist a subsequence \( \Lambda_2 \subset \tilde{\Lambda}_2 \) and a limit \( u^2 \in \dot{H}^1(\mathbb{R}) \) such that

\[
u_k(\cdot + z_k^2) \to u^2 \text{ locally uniformly for } k \uparrow \infty, \ k \in \Lambda_2.
\]

We now show the general construction, i.e. how one obtains the \((l + 1)\)th set of zeros from the construction after the \( l \)th step. Indeed, suppose the functions \( u^1, \ldots, u^l \), the sequences \( \Lambda_l \subset \cdots \subset \Lambda_1 \subset \mathbb{N} \) and the zeros \( z_k^1, \ldots, z_k^l \) of \( u_k \) for every \( k \in \Lambda_l \) have already been constructed. We now construct \( u^{l+1}, \Lambda_{l+1} \) and \( z_k^{l+1} \) for \( k \in \Lambda_{l+1} \). By assumption, none of the limits \( u^l, 1 \leq l \leq l \), satisfies (11). Hence, there exists \( \varepsilon_l > 0 \) such that for every \( s > 0 \) we can find \( s_1, \ldots, s_l \geq s \) with the property:

\[\left( u^l(s_j) \leq -\varepsilon_l < 0 \quad \text{or} \quad u^l(-s_j) \geq \varepsilon_l > 0 \right) \text{ for every } 1 \leq j \leq l.
\]

By uniform convergence, we also deduce that for every \( s > 0 \) there exists an index \( k_s \in \Lambda_l \) such that for every \( 1 \leq j \leq l \) and every \( k \geq k_s \) with \( k \in \Lambda_l \):

\[
sup_{[-s_j,s_j]} |\nu_k(\cdot + z_k^l) - u^l| \leq \frac{s}{2} \quad \text{and} \quad \min_{1 \leq i \neq j \leq l} |z_k^i - z_k^j| \geq 4 \max_{1 \leq j \leq l} s_j.
\]

15
In particular, for every \( s := n \in \mathbb{N} \) we choose as above \( s_1, \ldots, s_l \geq n \) and \( k := k_n \in \Lambda_l \) (again, \( \{k_n\}_{n \uparrow \infty} \) is to be chosen increasing). Then we deduce that for all \( 1 \leq j \leq l \) and \( k \in \Lambda_l \):

\[
    u_k(s_j + z_k^j) < 0 \quad \text{or} \quad u_k(-s_j + z_k^j) > 0,
\]

and the \( l \) intervals \( \{I_j := [z_k^j - s_j, z_k^j + s_j]\}_{1 \leq j \leq l} \) are disjoint.

Since \( u_k \) satisfies (11), there exists a new zero \( z_k^{j+1} \in Z_k \setminus \bigcup_{j=1}^{l} I_j \) of \( u_k \). Indeed, let us assume (after a rearrangement) that these intervals are ordered \( I_1 < I_2 < \cdots < I_l \). If there is no zero to the left of \( I_1 \) (i.e., on \( (-\infty, z_k^1 - s_1] \) and in-between these \( l \) intervals (i.e., on \( \bigcup_{j=1}^{l-1} [z_k^j + s_j, z_k^{j+1} - s_{j+1}] \)), then \( u_k \) must have a negative sign at the right endpoint of each interval \( I_j \) (i.e., \( u_k(z_k^j + s_j) < 0 \)) with \( 1 \leq j \leq l \). In particular, there must be a zero of \( u_k \) at the right of \( I_l \), that we call \( z_k^{l+1} \).

Set \( \tilde{\Lambda}_{l+1} = \{k_n \mid n \in \mathbb{N}\} \subset \Lambda_l \). Then

\[
    \min_{1 \leq j \leq l} |z_k^j - z_k^{j+1}| \to \infty \quad \text{as} \quad k \uparrow \infty, \quad k \in \tilde{\Lambda}_{l+1}.
\]

Finally, by Step 1, there exist \( \Lambda_{l+1} \subset \tilde{\Lambda}_{l+1} \) and \( u^{l+1} \) such that

\[
    u_k(- + z_k^{l+1}) \to u^{l+1} \quad \text{locally uniformly in} \; \mathbb{R} \; \text{as} \; k \uparrow \infty, \; k \in \Lambda_{l+1},
\]

which finishes the construction at the level \( l + 1 \).

**Step 3: Construction of vanishing diagonal sequence.** We prove that the assumption in Step 2 (i.e. the assumption that no accumulation point of a sequence of translates of \( \{u_k\}_{k \uparrow \infty} \) satisfies (11)) leads to a contradiction:

Consider the construction done in Step 2. The sequence \( \{u^l\}_{l \uparrow \infty} \) is uniformly bounded in \( H^1(\mathbb{R}) \). Hence, as in Step 1, there is a subsequence \( \Lambda \subset \mathbb{N} \) and a function \( u \) such that \( u^l \to u \) locally uniformly for \( l \uparrow \infty, \; l \in \Lambda \). In the following, we prove that \( u \equiv 0 \) on \( \mathbb{R} \) (in particular (11) is satisfied). Indeed, we first observe that \( 0 = u^l(0) \to u(0) \) as \( l \uparrow \infty, \; l \in \Lambda \); thus, \( u(0) = 0 \). Let now \( a > 0 \) and we want to prove that \( u(a) = 0 \). For that, let \( l \in \Lambda \) and \( k \in \Lambda_l \). Then for \( 1 \leq j \leq l \),

\[
    \frac{|u_k(a + z_k^j)|^2}{a} = \frac{|u_k(a + z_k^j) - u_k(z_k^j)|^2}{a} \leq \int_{z_k^j}^{a + z_k^j} |\frac{d}{ds}u_k|^2 ds.
\]

For \( k = k(a) \in \Lambda \) sufficiently large, the intervals \( \{[z_k^j, a + z_k^j]\}_{1 \leq j \leq l} \) are disjoint and we have

\[
    \sum_{1 \leq j \leq l} \frac{|u_k(a + z_k^j)|^2}{a} \leq \sum_{1 \leq j \leq l} \int_{z_k^j}^{a + z_k^j} |\frac{d}{ds}u_k|^2 ds \leq \int_{\mathbb{R}} |\frac{d}{ds}u_k|^2 ds.
\]

Letting \( k \uparrow \infty, \; k \in \Lambda_l \), it follows

\[
    \sum_{1 \leq j \leq l} \frac{|u^l(a)|^2}{a} \leq \limsup_{k \uparrow \infty} \int_{\mathbb{R}} |\frac{d}{ds}u_k|^2 ds < \infty.
\]
We may now let $t \uparrow \infty$, $t \in \Lambda$, and deduce that $u'(a) \to 0$. In particular, this shows $u(a) = 0$. The same argument adapts to the case $a < 0$, so that one concludes $u \equiv 0$ in $\mathbb{R}$.

Therefore, taking a diagonal sequence of the functions constructed in Step 2, one can then find a family $\{u_k(\cdot + x_i^k)\}_{i \in \Lambda}$ converging (locally uniformly) to the limit function $u \equiv 0$ that satisfies (11) in contradiction to our assumption.

The following lemma reduces the problem of finding admissible limits (i.e., satisfying the limit condition (1)) for a sequence of vector fields $\{m_k: \Omega \to S^2\}_{k \uparrow \infty}$ to shifting the $x_3$-average $\bar{m}_{2,k}$ of the second component $m_{2,k}$:

**Lemma 3.** Let $m \in \dot{H}^1(\Omega, \mathbb{S}^2)$ satisfy the limit condition $m'(\pm \infty, \cdot) = (\cos \theta, 0)$ in the $(m_1m_3)$-components in the sense of (2) for some angle $\theta \in (0, \pi)$. Then

$$\int_{\Omega} ||m_2| - \sin \theta|^2 dx < \infty.$$ 

If additionally the $x_3$-average $\bar{m}_2$ of $m_2$ satisfies (11) (i.e. $\bar{m}_2$ changes sign), then we have

$$m(\pm \infty, \cdot) = m_{\theta}^\pm.$$

**Remark 2.** (i) Note that the assumption $\theta \notin \{0, \pi\}$ is crucial: If we consider $m: \Omega \to \mathbb{S}^2$ given by $m_3 \equiv 0$,

$$m_1(x) = \begin{cases} \cos(\frac{\pi}{2}x_1) & \text{if } |x_1| \leq 1, \\ 1 - \frac{|x_1|}{1 + x_1} & \text{if } |x_1| > 1, \end{cases} \quad m_2(x) = \begin{cases} \sin(\frac{\pi}{2}x_1) & \text{if } |x_1| \leq 1, \\ \text{sgn}(x_1)\sqrt{1 - m_1^2(x)} & \text{if } |x_1| > 1, \end{cases}$$

then $m'(\pm \infty, \cdot) = (1, 0)$ (in the sense of (2)), and $m \in \dot{H}^1(\Omega, \mathbb{S}^2)$ since

$$\int_{\Omega} |\nabla m|^2 dx = 2 \int_{\mathbb{R}} \frac{|\frac{d}{dx}m_1|^2}{1 - m_1^2} dx \leq C + 4 \int_{1}^{\infty} \frac{|\frac{d}{dx}m_1|^2}{1 - m_1} dx < \infty,$$

but $\int_{\Omega} m_2^2 dx = \infty$, so that (2) fails for $m_2$.

(ii) Under the hypothesis of Lemma 3, in the case $\theta \in \{0, \pi\}$, by Remark 1 one may still conclude that $m \in \{\pm e_1\}$ provided that $\nabla \cdot (m'1_\Omega) = 0$ in $\mathcal{D}'(\mathbb{R}^2)$ (i.e. $m \in \mathcal{X}_0$).

**Proof of Lemma 3.** By $m_1^2 + m_2^2 + m_3^2 = 1 = \sin^2 \theta + \cos^2 \theta$ and the triangle inequality we have:

$$\int_{\Omega} |m_2^2 - \sin^2 \theta|^2 dx \leq 2 \int_{\Omega} |m_1^2 - \cos^2 \theta|^2 + m_3^4 dx$$

$$\leq 8 \int_{\Omega} |m_1 - \cos \theta|^2 + m_3^2 dx < \infty,$$

where we used

$$|m_1^2 - \cos^2 \theta| = |m_1 + \cos \theta| |m_1 - \cos \theta| \leq 2|m_1 - \cos \theta|.$$
Together with (23), this finally yields
\[ m'(\pm \infty, \cdot) = (\cos \theta, 0) \text{ and } |m_3| \leq 1. \] Since
\[ |m_3^2 - \sin^2 \theta| = ||m_2| - \sin \theta| |m_2| + \sin \theta| \geq \sin \theta |m_2| - \sin \theta| \text{ and } \theta \in (0, \pi), \]

it follows that
\[ \int_{\Omega} ||m_2| - \sin \theta|^2 \, dx \leq \frac{1}{\sin \theta} \int_{\Omega} |m_2^2 - \sin^2 \theta|^2 \, dx < \infty. \]

This proves the first part of the lemma. To establish the second part, we note that due to
\[ ||m_2| - |\bar{m}_2|| \leq |m_2 - \bar{m}_2| \]
we have
\[ \int_{\mathbb{R}} ||\bar{m}_2| - \sin \theta|^2 \, dx_1 = \frac{1}{2} \int_{\Omega} ||\bar{m}_2| - \sin \theta|^2 \, dx \]
\[ \leq \int_{\Omega} |m_2 - \bar{m}_2|^2 + ||m_2| - \sin \theta|^2 \, dx < \infty, \quad (22) \]

where we used the Poincaré-Wirtinger inequality
\[ \int_{\mathbb{R}} \int_{-1}^{1} |m_2 - \bar{m}_2|^2 \, dx_3 \, dx_1 \leq C \int_{\Omega} |\partial_{x_3} m_2|^2 \, dx. \quad (23) \]

Since \( ||\bar{m}_2||_{H^1(\mathbb{R})} = ||\bar{m}_2||_{H^1(\mathbb{R})} \leq \frac{1}{\sqrt{2}} ||m_2||_{H^1(\Omega)} < \infty \), we deduce with help of (22) that
\[ |\bar{m}_2| - \sin \theta \in H^1(\mathbb{R}); \text{ in particular, } \bar{m}_2(s) \to \sin \theta > 0 \text{ as } |s| \to \infty. \]

Under the additional assumption \( \liminf_{s \to \infty} \bar{m}_2(s) \geq 0 \) and \( \limsup_{s \to -\infty} \bar{m}_2(s) \leq 0 \), we deduce from \( |\bar{m}_2(s)| \to \sin \theta > 0 \text{ as } |s| \to \infty \) that \( |\bar{m}_2(s)| = \bar{m}_2(s) \) and \( |\bar{m}_2(-s)| = -\bar{m}_2(-s) \)
if \( s \) is sufficiently large, so that (22) translates into
\[ \int_{\mathbb{R}} |\bar{m}_2 + \sin \theta|^2 \, dx_1 + \int_{\mathbb{R}} |\bar{m}_2 - \sin \theta|^2 \, dx_1 < \infty. \]

Together with (23), this finally yields
\[ \int_{\Omega} |m_2 + \sin \theta|^2 \, dx + \int_{\Omega} |m_2 - \sin \theta|^2 \, dx \]
\[ \leq 2 \int_{\Omega} |m_2 - \bar{m}_2|^2 \, dx + 4 \int_{\mathbb{R}} |\bar{m}_2 + \sin \theta|^2 \, dx_1 + 4 \int_{\mathbb{R}} |\bar{m}_2 - \sin \theta|^2 \, dx_1 < \infty. \]

\[ \square \]

We now prove Proposition 1. In fact, we shall prove it in form of the following proposition that treats all the cases at once: (i) corresponds to \( \eta_k \downarrow 0 \), (ii) corresponds to \( \eta_k \equiv \eta \in (0, 1) \), and (iii) corresponds to \( \eta_k \equiv 0 \).

**Proposition 2.** Suppose that the sequences \( \{\theta_k\}_{k=\infty} \subset (0, \pi) \), \( \{\eta_k\}_{k=\infty} \subset [0, 1) \) satisfy \( \theta_k \to \theta \) and \( \eta_k \to \eta \) as \( k \to \infty \)

\[ \text{with } \theta \in (0, \pi) \text{ whenever } \eta \in (0, 1). \quad (24) \]

Suppose further that the sequence \( \{m_k\}_{k=\infty} \subset \dot{H}^1(\Omega, \mathbb{S}^2) \) satisfies
\[ m_k \in \begin{cases} X^{\theta_k}, & \text{for } \eta_k \in (0, 1), \\ X_0 \cap X^{\theta_k}, & \text{for } \eta_k = 0, \end{cases} \quad (25) \]

18
and
\[
\begin{cases}
E_{\eta_k}(m_k), & \text{for } \eta_k > 0, \\
E_0(m_k), & \text{for } \eta_k = 0,
\end{cases}
\] is bounded as \( k \to \infty \). \hfill (26)

Then there exist zeros \( x_{1,k} \) of \( \bar{m}_{2,k} \) such that after passage to a subsequence, there exists \( m \in \dot{H}^1(\Omega, S^2) \) such that
\[
m_k(\cdot + x_{1,k}, \cdot) \rightharpoonup m \quad \text{weakly in } \dot{H}^1(\Omega) \text{ and weak-}* \text{ in } L^\infty(\Omega),
\]
\[
h(m_k) \begin{cases}
\to h(m), & \text{for } \eta \in (0, 1), \\
\to 0, & \text{for } \eta = 0,
\end{cases}
\]
in \( L^2(\Omega) \), and
\[
m \in \begin{cases}
X^\theta, & \text{for } \eta \in (0, 1), \\
X_0 \cap X^{\hat{\theta}}, & \text{for } \eta = 0,
\end{cases}
\]
with \( \hat{\theta} \in [0, \pi] \).\(^8\)

**Proof of Proposition 2.** We divide the proof in several steps:

**Step 1:** *Compactness of translates of averages \( \{\bar{m}_{2,k}\} \).* According to (26), we have that
\[
\int_{\mathbb{R}} |\frac{d}{dx_1} \bar{m}_{2,k}|^2 dx_1 \quad \text{is bounded for } k \uparrow \infty,
\]
i.e. (9) for \( \bar{m}_{2,k} \). From (25) we obtain
\[
\int_{\mathbb{R}} |\bar{m}_{2,k} + \sin \theta_k|^2 dx_1 + \int_{\mathbb{R}} |\bar{m}_{2,k} - \sin \theta_k|^2 dx_1 < \infty \quad \text{for each } k \in \mathbb{N}.
\]
Since \( \theta_k \in (0, \pi) \), this implies in particular (10) for \( \bar{m}_{2,k} \). Hence by Lemma 1, there exist zeros \( x_{1,k} \) of \( \bar{m}_{2,k} \) and \( u \in \dot{H}^1(\mathbb{R}) \cap C(\mathbb{R}) \) s.t. for a subsequence
\[
\bar{m}_{2,k}(\cdot + x_{1,k}, \cdot) \rightharpoonup u \quad \text{weakly in } \dot{H}^1(\mathbb{R}) \text{ and locally uniformly},
\]
with \( u \) satisfying (11).

**Step 2:** *Convergence of \( \{m_k(\cdot + x_{1,k}, \cdot)\} \).* Because of (26), by standard weak-compactness results, there exists \( m \in \dot{H}^1(\Omega) \cap L^\infty(\Omega) \) s.t. for a subsequence
\[
m_k(\cdot + x_{1,k}, \cdot) \rightharpoonup m \quad \text{weakly in } \dot{H}^1(\Omega) \text{ and weak-}* \text{ in } L^\infty(\Omega).
\]
By Rellich’s compactness result,
\[
m_k(\cdot + x_{1,k}, \cdot) \rightharpoonup m \quad \text{in } L^2_{\text{loc}}(\Omega) \text{ and a.e.,}
\]
\(^8\)One might have that \( \hat{\theta} \neq \theta \), see Remark 3 (ii).
so that in particular $m_k \in H^1(\Omega, S^2)$ yields $m \in H^1(\Omega, S^2)$. We thus may identify $u$ as $\tilde{m}_2$, i.e.
\[
\tilde{m}_2 \equiv u \quad \text{in} \quad \mathbb{R},
\]
so that $\tilde{m}_2$ satisfies (11).

To simplify notation, we identify $m_k$ with its translate $m_k(\cdot + x_{1,k}, \cdot)$ in the sequel of the proof.

**Step 3:** If $\eta \in (0, 1)$, we show that $m \in X^\theta$ and compactness of $\{h(m_k)\}$. Indeed, in this case, (26) yields in particular (recall that $\eta \in (0, 1)$)
\[
\left\{ \int_{\Omega} |m_{1,k} - \cos \theta_k|^2 + m_{3,k}^2 \, dx \right\}_k \text{ is bounded as } k \uparrow \infty,
\]
so that Fatou’s lemma and Step 2 lead to:
\[
\int_{\Omega} |m_1 - \cos \theta|^2 + m_3^2 \, dx < \infty,
\]
that is, $m'(\pm \infty, \cdot) = (\cos \theta, 0)$. Since by assumption (24), $\theta \in (0, \pi)$, and since $\tilde{m}_2$ satisfies (11), Lemma 3 yields $m(\pm \infty, \cdot) = (\cos \theta, \pm \sin \theta, 0)$. Hence, we indeed have $m \in X^\theta$. For proving compactness of stray fields, we note that (26) yields in particular $^9$
\[
\left\{ \int_{\mathbb{R}^2} |h(m_k)|^2 \right\}_k \text{ is bounded as } k \uparrow \infty.
\]
Hence there exists $h \in L^2(\Omega)$ s.t. for a subsequence
\[
h(m_k) \rightharpoonup h \quad \text{weakly in } L^2(\mathbb{R}^2).
\]
Passing to the limit in the distributional formulation $\nabla \cdot (h(m_k) + m'_k 1_\Omega) = 0$, $\nabla \times h(m_k) = 0$ to obtain $\nabla \cdot (h + m' 1_\Omega) = 0$, $\nabla \times h = 0$ in $\mathcal{D}'(\mathbb{R}^2)$, and using uniqueness of the stray-field of $m$ with (1), we learn that $h = h(m)$.

**Step 4:** If $\eta = 0$, we show that $h(m_k) \to 0$ in $L^2(\mathbb{R}^2)$ and $m \in X_0 \cap X_\tilde{\theta}$ for some $\tilde{\theta} \in [0, \pi]$. Indeed, in this case, (26) yields in particular (recall that $m_k \in X_0$ yields $h(m_k) \equiv 0$):
\[
\int_{\mathbb{R}^2} |h(m_k)|^2 \, dx \to 0,
\]
so that passing to the limit in the distributional formulation $\nabla \cdot (h(m_k) + m'_k 1_\Omega) = 0$ we learn that $\nabla \cdot (m' 1_\Omega) = 0$ in $\mathcal{D}'(\mathbb{R}^2)$. Since $m \in \dot{H}^1(\Omega) \cap L^\infty(\Omega)$, this yields
\[
\nabla \cdot m' = 0 \quad \text{in } \Omega, \quad m_3 = 0 \quad \text{on } \partial \Omega.
\]
(28)
On the other hand, $\nabla \cdot (m' 1_\Omega) = 0$ in $\mathcal{D}'(\mathbb{R}^2)$ implies $\frac{d}{dx_1}\tilde{m}_1 = 0$ on $\mathbb{R}$, so that there exists $\tilde{\theta} \in [0, \pi]$ with
\[
\tilde{m}_1 = \cos \tilde{\theta} \quad \text{on } \mathbb{R}.
\]
(29)

\[\text{Note that } h(m(\cdot + z_1, \cdot)) \equiv h(m)(\cdot + z_1, \cdot) \text{ by uniqueness of } L^2 \text{ stray-fields in (4) associated to configurations satisfying (1).}\]
We note that in general, $\tilde{\theta} \neq \theta = \lim_{\theta \to \infty} \theta_k$. By the Poincaré-Wirtinger inequality in $x_3$ we obtain from (29):

$$\int_{\Omega} |m_1 - \cos \tilde{\theta}|^2 dx \leq C \int_{\Omega} |\partial_{x_3} m_1|^2 dx < \infty.$$  \hspace{1cm} (30)$$

By the Poincaré inequality in $x_3$, we obtain from (28):

$$\int_{\Omega} m_3^2 dx \leq C \int_{\Omega} |\partial_{x_3} m_3|^2 dx < \infty.$$  \hspace{1cm} (31)$$

Hence we have $m'(\pm \infty, \cdot) = (\cos \tilde{\theta}, 0)$. To conclude, we distinguish two cases:

**Case 1:** $\tilde{\theta} \in (0, \pi)$. In this case, we may conclude by Lemma 3 that $m(\pm \infty, \cdot) = (\cos \tilde{\theta}, \pm \sin \tilde{\theta}, 0)$ as in case of $\eta \in (0, 1)$. We thus obtain $m \in X_0 \cap X^\theta$.

**Case 2:** $\tilde{\theta} \in \{0, \pi\}$. In this case, we apply Remark 1 to conclude from (29) that $m$ is one of the constant functions $\pm \mathbf{e}_1$ and thus trivially lies in $X_0 \cap X^\theta$. \hfill \Box

**Remark 3.** (i) *The assumption $\theta \in (0, \pi)$ whenever $\eta \in (0, 1)$ in (24) is due to Remark 2, since in general the condition $m_2(\pm \infty, \cdot) = \pm \sin \theta$ fails if $\theta \in \{0, \pi\}$. However, if $\theta \in \{0, \pi\}$, one gets a weaker statement concerning the behavior of $\tilde{m}_2$ at $\pm \infty$:

**Claim.** Suppose that the sequences $\{\theta_k\}_{k=1}^\infty \subset (0, \pi), \{\eta_k\}_{k=1}^\infty \subset (0, 1)$ satisfy

$$\theta_k \to \theta \text{ and } \eta_k \to \eta \text{ with } \theta \in \{0, \pi\} \text{ and } \eta \in (0, 1).$$

Consider a sequence $\{m_k\}_{k=1}^\infty \subset H^1(\Omega, S^2)$ for which $m_k \in X^\theta_k$ and $\{E_{\eta_k}(m_k)\}$ is bounded. Then there exists $m \in \dot{H}^1(\Omega, S^2)$ such that after passage to a subsequence:\textsuperscript{10}

$$m_k \rightharpoonup m \text{ weakly in } \dot{H}^1(\Omega) \text{ and weak-* in } L^\infty(\Omega),$$

$$h(m_k) \rightharpoonup h(m) \text{ weakly in } L^2(\mathbb{R}^2),$$

$$E_{\eta}(m) < \infty,$$

$$\tilde{m}_2(x) \to 0 \text{ as } |x| \to \infty.$$  \hspace{1cm} (29)$$

Indeed, we can essentially proceed as in the proof of Steps 1, 2 and 3 in Proposition 2. However, note that there is no need to apply Lemma 1; moreover, the application of Lemma 3 (at Step 3) is no longer possible. Instead, note that $\tilde{m}_1 - \cos \theta, \tilde{m}_3 \in H^1(\mathbb{R})$ yields $\lim_{|x_1| \to \infty} \tilde{m}_1(x_1) = \cos \theta \in \{\pm 1\}$ and $\lim_{|x_1| \to \infty} \tilde{m}_3(x_1) = 0$. Therefore,

$$1 = \lim_{|x_1| \to \infty} \sup_{-1}^1 |m(x)| dx_x \geq \lim_{|x_1| \to \infty} \sup_{-1}^1 \left| (\tilde{m}_1, \tilde{m}_2, \tilde{m}_3)(x_1) \right| = \left| (1, \lim_{|x_1| \to \infty} \tilde{m}_2(x_1), 0) \right|,$$

i.e., $\lim_{|x_1| \to \infty} \tilde{m}_2(x_1) = 0$. \hfill \Box

\textsuperscript{10}No translation in $x_1$-direction is required here.
(ii) Note that in the case \( \eta = 0 \), the angle \( \tilde{\theta} = \theta_m \) associated to the limiting configuration \( m \) via (7) in general does not coincide with the limit \( \theta \) of the sequence \( \theta_k \). In particular, in the situation of Proposition 1 (i) for \( \theta_k \equiv \alpha = \theta \), the limit angle \( \tilde{\theta} = \theta_m \) describes the amount of asymmetric rotation in the wall core. Hence, the possibility of having \( \tilde{\theta} \neq \theta \) is directly related to observing a non-trivial behavior of the reduced model (14).

However, there are also cases in which \( \theta = \lim_k \theta_k \) coincides with the limit angle \( \tilde{\theta} \), as can be seen in the statement of Proposition 1 (iii).

**Proof of Proposition 1:** Statements (i) and (ii) are an immediate consequence of Proposition 2 by letting \( \theta_k \equiv \alpha \).

Statement (iii) follows from Remark 1, if there exists a constant subsequence \( \theta_k \in \{0, \pi\} \). Otherwise, we find a convergent subsequence \( \{\theta_k\}_{k \uparrow \infty} \subset (0, \pi) \) to which we apply Proposition 2 with \( \eta_k \equiv 0 \). In this latter case, not relabeling the subsequence, it remains to prove that the limit \( \theta := \lim_k \theta_k \) satisfies \( \theta = \theta_m \), i.e., \( m \in X^\theta \). Indeed, exploiting (7) and (27), one obtains

\[
\cos \theta \leftarrow \cos \theta_k \equiv \bar{m}_{1,k}(\cdot + x_{1,k}) \rightarrow \bar{m}_1 \equiv \cos \theta_m \quad \text{as} \quad k \uparrow \infty.
\]

Since \( \theta, \theta_m \in [0, \pi] \), this yields \( \theta = \theta_m \).

---

### 3.2 Existence of minimizers

Due to the compactness statements in Proposition 1, one obtains existence of minimizers for \( E_\eta \), \( E_{\text{asym}}(\theta) \) and \( E_0 \).

**Theorem 3.**

- For fixed parameters \( \eta \in (0, 1) \) and \( \alpha \in (0, \frac{\pi}{2}] \), there exists a minimizer of \( E_\eta \) over the set \( X^\alpha \).

- For \( \theta \in [0, \pi] \) fixed, there exists a minimizer of \( E_{\text{asym}}(\theta) \) over the (non-empty, cf. Appendix) set \( m \in X_0 \) with \( \theta_m = \theta \).

- The \( \Gamma \)-limit energy \( E_0 \) admits a minimizer over \( X_0 \). The optimal angle \( \theta \) in the minimization problem (14) is attained.

**Proof.** Observe that the functionals \( E_\eta \) and \( \{m \mapsto \int_\Omega |\nabla m|^2 \, dx\} \) are lower-semicontinuous with respect to the weak convergence obtained in Proposition 1. Hence, the first two statements in Theorem 3 follow immediately by the direct method in the calculus of variations, i.e. by applying the compactness results in Proposition 1 to minimizing sequences.

For the third statement, we need an auxiliary lemma that we prove using the existence of minimizers of \( E_{\text{asym}}(\theta) \) we have just shown:

**Lemma 4.** The map \( \theta \in [0, \pi] \mapsto E_{\text{asym}}(\theta) \in \mathbb{R}_+ \) is lower semicontinuous.
Proof of Lemma 4. This immediately follows from Proposition 1 (iii) by considering for each sequence \( \{ \theta_k \in [0, \pi] \}_{k \uparrow \infty} \), a sequence \( \{ m_k \in X_0 \}_{k \uparrow \infty} \) of minimizers of \( E_{\text{asy}}(\theta_k) \) for each \( k \).

Now, the third statement in Theorem 3 again follows by the direct method in the calculus of variations, since \( E_0 \) is just a continuous perturbation of \( E_{\text{asy}} \).

4 Proof of \( \Gamma \)-convergence

4.1 Lower bound. Proof of Theorem 1

To establish the lower bound (12), one has to estimate the exchange term in \( E_\eta(m_\eta) \) as well as stray-field and anisotropy energy from below as \( \eta \downarrow 0 \). If \( m \) is the limit of \( m_\eta \) (in the weak \( H^1 \)-topology), then the exchange term will be estimated as \( \eta \downarrow 0 \) by \( \int_\Omega |\nabla m|^2 \, dx \), while the stray-field and anisotropy energy will be estimated by \( \lambda E_{\text{sym}}(\alpha - \theta_m) \), where \( \theta_m \) is associated to \( m \in X_0 \) via (7).

Let \( C > 0 \) always denote a universal, generic constant. W.l.o.g. we may assume \( E_\eta(m_\eta) \leq C_0 < \infty \) for some \( C_0 > 0 \) and \( m_\eta \rightharpoonup m \) in \( L^2_{\text{loc}}(\Omega) \) and a.e. in \( \Omega \) as \( \eta \downarrow 0 \).

**Step 1: Exchange energy.** We first address estimating the exchange energy from below. Since \( m_\eta \rightharpoonup m \) in \( H^1(\Omega) \) as \( \eta \downarrow 0 \), we obviously have

\[
\int_\Omega |\nabla m|^2 \, dx \leq \liminf_{\eta \downarrow 0} \int_\Omega |\nabla m_\eta|^2 \, dx,
\]

by weak lower-semicontinuity of the \( L^2 \) norm of \( \{\nabla m_\eta\}_{\eta \downarrow 0} \).

**Step 2: Choice of test function.** Now it remains to estimate both stray-field and anisotropy energy in \( E_\eta(m_\eta) \) from below by \( 2\pi \lambda (\cos \theta_m - \cos \alpha)^2 \).

Here the idea is to approximate the limit

\[
\cos \theta_m - \cos \alpha = \int_{-1}^1 \int_{-1}^1 (m_1 - \cos \alpha) \, dx_3 \, dx_1
\]

by \( \int_{-1}^1 \int_{-1}^1 (m_{1,\eta} - \cos \alpha) \, dx_3 \, dx_1 \) and to define a suitable test function \( \zeta: \mathbb{R}^2 \to \mathbb{R} \), that captures the profile of the tails of a Néel wall (i.e. when \( |x_1| \geq 1 \)) and has the property that

\[
\int_{-1}^1 \int_{-1}^1 (m_{1,\eta} - \cos \alpha) \, dx_3 \, dx_1 = \int_{-1}^1 \int_{-1}^1 (m_\eta' - (\cos \alpha, 0)) \cdot \nabla \zeta \, dx_3 \, dx_1.
\]

In this way, the stray-field energy will control \( 2\pi \lambda (\cos \theta_m - \cos \alpha)^2 \). Note that the argument here is similar to the one used in [19].
Lemma 5. Let $a > 1$ and $\zeta_0 : \mathbb{R} \to \mathbb{R}$ be the odd piecewise affine function defined by

\[
\zeta_0(x_1) := \begin{cases} 
  x_1, & 0 < x_1 < 1, \\
  1, & 1 \leq x_1 < a, \\
  -\frac{1}{a}(x_1 - 2a), & a \leq x_1 < 2a, \\
  0, & 2a \leq x_1
\end{cases}
\]  

(see Figure 5). Let $\zeta : \mathbb{R}^2 \to \mathbb{R}$ be given by $\zeta(x_1, x_3) = \zeta_0(x_1)$ on $\Omega$ and harmonically extended to $\mathbb{R}^2$ away from $\Omega$, i.e. $\zeta$ satisfies

\[
\begin{aligned}
\Delta \zeta &= 0 & \text{on } \mathbb{R}^2 \setminus \bar{\Omega}, \\
\zeta(\cdot, \pm 1) &= \zeta_0 & \text{on } \mathbb{R}.
\end{aligned}
\]

Then we have

\[
\int_{\mathbb{R}^2} |\nabla \zeta|^2 \, dx \leq \frac{8}{\pi} \ln a + C
\]

for some constant $C = O(1)$ as $a \uparrow \infty$.

Remark 4. Problem (34) can be solved explicitly via Fourier transform in the $x_1$-variable:

\[
(F_{x_1} f)(k_1) := \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} f(x_1)e^{-ik_1 x_1} \, dx_1, \quad k_1 \in \mathbb{R},
\]

where $f : \mathbb{R} \to \mathbb{R}$. In fact, (34) becomes a second-order ODE for $F_{x_1}(\zeta)$ in the $x_3$-variable. Imposing that $\zeta \in H^1(\mathbb{R}^2 \setminus \Omega)$, we deduce:

\[
F_{x_1}(\zeta)(k_1, x_3) = F_{x_1}(\zeta_0)(x_1)e^{-|k_1|(|x_3|-1)}, \quad k_1 \in \mathbb{R}, \ |x_3| > 1.
\]

![Figure 5: Test function $\zeta_0$](image)

Proof of Lemma 5. First we show

\[
\int_{\mathbb{R}^2} |\nabla \zeta|^2 \, dx = 2 \left( \int_{\mathbb{R}} \left| \frac{d}{dx_1} \zeta_0 \right|^2 \, dx_1 + \int_{\mathbb{R}} \left| \frac{d}{dx_1} \zeta_0 \right|^2 \, dx_1 \right),
\]

where we define

\[
\int_{\mathbb{R}} \left| \frac{d}{dx_1} \frac{d}{dx_1} f \right|^2 \, dx_1 := \int_{\mathbb{R}} |k_1| \left| F_{x_1} f \right|^2 \, dk_1 \in [0, \infty], \quad f \in L^2(\mathbb{R}).
\]
Indeed, for the contribution from $\Omega$ we simply have
\[
\int_{\Omega} |\nabla \zeta|^2 \, dx \stackrel{\zeta=\zeta_0 \text{ in } \Omega \cap \Omega}{=} \int_{\Omega} |\nabla \zeta_0|^2 \, dx \, \zeta_0=\zeta_0(x_1) \, 2 \int_{\mathbb{R}} \left| \frac{d}{dx_1} \zeta_0 \right|^2 \, dx_1.
\]
Moreover, the contribution from $\mathbb{R}^2 \setminus \Omega$ can be computed using (37):
\[
\int_{\mathbb{R}^2 \setminus \Omega} |\nabla \zeta|^2 \, dx = 2 \int_{\mathbb{R} \times (1,\infty)} |\nabla \zeta|^2 \, dx
\]
\[
= 2 \int_{1}^{\infty} \int_{\mathbb{R}} \left| F_{x_1}(\nabla \zeta)(k_1, x_3) \right|^2 \, dk_1 \, dx_3
\]
\[
= 2 \int_{1}^{\infty} \int_{\mathbb{R}} \left| k_1 F_{x_1}(\zeta)(k_1, x_3) \right|^2 + |\partial_{x_3} F_{x_1}(\zeta)(k_1, x_3)|^2 \, dk_1 \, dx_3
\]
\[
= 2 \int_{1}^{\infty} \int_{\mathbb{R}} \left| k_1 \right| F_{x_1}(\zeta)(k_1, x_3)^2 + \left| k_1 \right| F_{x_1}(\zeta)(k_1, x_3)^2 \, dk_1 \, dx_3
\]
\[
\overset{(37)}{=} 2 \int_{\mathbb{R}} \left| k_1 \right| F_{x_1}(\zeta_0)(\zeta_0)^2 \left( \int_{1}^{\infty} 2 \left| k_1 \right| e^{-2 \left| k_1 \right| (x_3-1)} \, dx_3 \right) \, dk_1
\]
\[
= 2 \int_{\mathbb{R}} \left| \frac{d}{dx_1} \zeta_0 \right|^2 \, dx_1.
\]
Therefore (38) is established.

To prove (35), one first observes that $\int_{\mathbb{R}} \left| \frac{d}{dx_1} \zeta_0 \right|^2 \, dx_1$ remains bounded as $a \uparrow \infty$, so that the leading-order contribution to (38) is given by the homogeneous $\dot{H}^\frac{3}{2}$ norm of $\zeta_0$. Recall that the $\dot{H}^\frac{3}{2}$ norm can be expressed as
\[
\int_{\mathbb{R}} \left| \frac{d}{dx_1} \zeta_0 \right|^2 \, dx_1 = \min \left\{ \int_{\mathbb{R} \times \mathbb{R}_+} |\nabla \zeta|^2 \, dx \left| \zeta \in \dot{H}^1(\mathbb{R} \times \mathbb{R}_+), \tilde{\zeta}(\cdot, 0) = \zeta_0 \right. \right\}.
\]
(39)
Therefore, to estimate (39), we choose an admissible function $\tilde{\zeta}$:
\[
\tilde{\zeta}(x) = \tilde{\zeta}(r, \theta) := \zeta_0(r) \varphi(\theta), \quad x \in \mathbb{R} \times \mathbb{R}_+,
\]
where $(r, \theta)$ denote the polar coordinates of $x \in \mathbb{R} \times \mathbb{R}_+$ and $\varphi : [0, \pi] \rightarrow [-1, 1]$ is given by
\[
\varphi(\theta) = 1 - \frac{2}{\pi} \theta, \quad 0 \leq \theta \leq \pi.
\]
Observe that indeed $\tilde{\zeta}(\cdot, 0) = \zeta_0$ in $\mathbb{R}$ (since $\zeta_0$ is odd and $\varphi(0) = -\varphi(\pi) = 1$). Therefore, we may estimate
\[
\int_{\mathbb{R}} \left| \frac{d}{dx_1} \zeta_0 \right|^2 \, dx_1 \overset{(39)}{=} \int_{\mathbb{R} \times \mathbb{R}_+} |\nabla \zeta|^2 \, dx = \int_{0}^{\pi} \int_{0}^{\infty} \left( \left| \frac{\partial}{\partial r} \tilde{\zeta} \right|^2 + \left| \frac{1}{r} \frac{\partial}{\partial \theta} \tilde{\zeta} \right|^2 \right) r \, dr \, d\theta
\]
\[
= \int_{0}^{\pi} \varphi^2 \, d\theta \int_{0}^{\infty} \left| \frac{d}{dr} \zeta_0 \right|^2 r \, dr + \int_{0}^{\pi} \varphi^2 \, d\theta \int_{0}^{\infty} \zeta_0^2 \frac{dr}{r}
\]
\[
= \frac{4}{\pi} \ln a + \mathcal{O}(1),
\]
which yields the asserted scaling. \qed
Step 3: Stray-field and anisotropy energy. With the test function constructed in Step 2 we can establish the relation between $\lambda E_{sym}(\alpha - \theta_m)$ and stray-field/anisotropy energy. First we use the definition of $\zeta$ to rewrite

$$\int_{-1}^{1} \int_{-1}^{1} (m_{1, \eta} - \cos \alpha) \, dx_1 \, dx_3$$

$$= \frac{1}{4} \int_{-1}^{1} \int_{-1}^{1} (m_{1, \eta} - \cos \alpha) \, \partial_{x_1} \zeta \, dx_1 \, dx_3$$

$$= \frac{1}{4} \int_{\Omega} (m_{1, \eta} - \cos \alpha) \, \partial_{x_1} \zeta \, dx + \frac{1}{4a} \int_{((-2a, -a) \cup (a, 2a)) \times (-1, 1)} (m_{1, \eta} - \cos \alpha) \, dx$$

$$= \frac{1}{4} \int_{\Omega} m' \cdot \nabla \zeta \, dx + \frac{1}{4a} \int_{((-2a, -a) \cup (a, 2a)) \times (-1, 1)} (m_{1, \eta} - \cos \alpha) \, dx$$

$$\leq \frac{1}{4} \int_{\mathbb{R}^2} |h(m_{\eta})|^2 \, dx \left( \int_{\mathbb{R}^2} |\nabla \zeta|^2 \, dx \right)^{\frac{1}{2}} + \frac{1}{4a} \int_{\Omega} (m_{1, \eta} - \cos \alpha)^2 \, dx \leq \left( \frac{1}{2\pi} \ln a + O(1) \right) \int_{\mathbb{R}^2} |h(m_{\eta})|^2 \, dx$$

$$\leq \left( \frac{1}{4\pi} \ln a + O(1) \right) \int_{\mathbb{R}^2} |h(m_{\eta})|^2 \, dx + \left( \frac{1}{4a} \int_{\Omega} (m_{1, \eta} - \cos \alpha)^2 \, dx \right)^{\frac{1}{2}},$$

as $a \uparrow \infty$. If we now apply

$$\sqrt{\alpha} + \sqrt{\beta} \leq \sqrt{(1 + \delta) + \delta^{-2} \beta},$$

which holds\(^{11}\) for $0 < \delta \leq \frac{1}{2}$, $\alpha, \beta \geq 0$, to

$$\alpha = \left( \frac{1}{2\pi} \ln a + O(1) \right) \int_{\mathbb{R}^2} |h(m_{\eta})|^2 \, dx,$$

$$\beta = \frac{1}{4a} \int_{\Omega} (m_{1, \eta} - \cos \alpha)^2 \, dx,$$

we find

$$\left( \int_{-1}^{1} \int_{-1}^{1} (m_{1, \eta} - \cos \alpha) \, dx \right)^2 \leq \left( \frac{1}{2\pi} \ln a + O(1) \right) (1 + \delta) \int_{\mathbb{R}^2} |h(m_{\eta})|^2 \, dx$$

$$+ \frac{1}{4a} \int_{\Omega} (m_{1, \eta} - \cos \alpha)^2 \, dx.$$

Now, for $\delta \in (0, \frac{1}{2}]$ fixed, choose $a = a(\eta)$ such that

$$\frac{1}{4\pi a} = \lambda^{-1} \frac{1+\delta}{2\pi} \eta.$$

This implies $a \uparrow \infty$ as $\eta \downarrow 0$ and $\ln a = \frac{1}{\eta} + O(1)$ as $\eta \downarrow 0$.

\(^{11}\) Use $\sqrt{\alpha \beta} \leq \frac{1}{4a} + \frac{1}{4\pi} \beta$ and $\frac{1}{2} \leq \frac{1}{\eta} - 1$. 

26
Note that $\lambda \ln \frac{1}{\eta} \int_{\mathbb{R}^2} |h(m_\eta)|^2 dx \leq E_\eta(m_\eta)$ is uniformly bounded and thus $\int_{\mathbb{R}^2} |h(m_\eta)|^2 dx \to 0$ as $\eta \downarrow 0$. Together with $\cos \theta_m = \int_{-1}^1 \tilde{m}_1 dx_1 \leftrightarrow \int_{-1}^1 \tilde{m}_1,\eta dx_1$, we obtain:

$$(\cos \theta_m - \cos \alpha)^2 = \left( \liminf_{\eta \downarrow 0} \int_{-1}^1 \left( m_{1,\eta} - \cos \alpha \right) dx_1 dx_3 \right)^2$$

$$\leq \liminf_{\eta \downarrow 0} \left( \frac{1}{\eta^2} (1 + \delta) \ln a \int_{\mathbb{R}^2} |h(m_\eta)|^2 dx + \frac{1}{\eta} \int_{\Omega} (m_{1,\eta} - \cos \alpha)^2 dx \right)$$

$$= (1 + \delta) \liminf_{\eta \downarrow 0} \left( \frac{1}{\eta^2} \ln \frac{1}{\eta} \int_{\mathbb{R}^2} |h(m_\eta)|^2 dx + \lambda^{-1} \frac{1}{\eta^2} \int_{\Omega} (m_{1,\eta} - \cos \alpha)^2 dx \right).$$

Letting now $\delta \downarrow 0$, it follows:

$$2\pi \lambda (\cos \theta_m - \cos \alpha)^2 \leq \liminf_{\eta \downarrow 0} \left( \lambda \ln \frac{1}{\eta} \int_{\mathbb{R}^2} |h(m_\eta)|^2 dx + \eta \int_{\Omega} (m_{1,\eta} - \cos \alpha)^2 dx \right). \quad (40)$$

**Step 4: Conclusion.** By combining (32) and (40) one sees

$$E_0(m) \leq \liminf_{\eta \downarrow 0} \int_{\Omega} |\nabla m_\eta|^2 dx + \liminf_{\eta \downarrow 0} \left( \lambda \ln \frac{1}{\eta} \int_{\mathbb{R}^2} |h(m_\eta)|^2 dx + \eta \int_{\Omega} (m_{1,\eta} - \cos \alpha)^2 dx \right)$$

$$\leq \liminf_{\eta \downarrow 0} E_\eta(m_\eta),$$

i.e. the lower bound (12) is proven.

### 4.2 Upper bound

For each $m \in X_0$ we construct a recovery sequence $\{m_\eta\}_{\eta \downarrow 0} \subset X^\alpha$ such that $m_\eta \to m$ in $\dot{H}^1(\Omega)$ and (13) holds. For that, in the general case $\theta_m \not\in \{0, \alpha, \pi\}$, the basic guideline will be a decomposition of $\Omega$ into several parts (as shown in Figure 6): We consider the regions

![Figure 6: Construction of recovery sequence](image)

$\Omega_A := [-a, a] \times (-1, 1)$,

$\Omega_I := \left([-a+1, -a] \cup [a, a+1]\right) \times (-1, 1)$,

$\Omega_T := \left([-\frac{a+1}{\eta}, -(a+1)] \cup [a+1, \frac{a+1}{\eta}]\right) \times (-1, 1)$,
where $a$ is a parameter of order $\ln \frac{\gamma}{\eta} \gg 1$ (to be chosen explicitly at Step 1 below).

- The (core) region $\Omega_A$ stands for the asymmetric part of the transition layer $m_\eta$: Here, $m'_\eta$ is of vanishing divergence (so, a stray-field free configuration) with an asymptotic angle transition from $-\theta_m$ to $\theta_m$ (as $\eta \downarrow 0$) so that the leading-order term is driven by the exchange energy.

- The (tail) region $\Omega_T$ corresponds to the symmetric part of the transition layer $m_\eta$ that mimics the tails of a symmetric Néel wall. Here, the leading order term of the energy is driven by the stray field, the transition angle covering the range $[-\alpha, -\theta_m]$ (at the left) and $[\theta_m, \alpha]$ (at the right), respectively.

- The (intermediate) region $\Omega_I$ is necessary for the transition between the core of $m_\eta$ and the tails of a Néel wall. This is because the asymmetric core of $m_\eta$ and the symmetric tails will not fit together perfectly (on $\Omega_A$, the angle transition is $2\theta_m + o(1)$ and not exactly $2\theta_m$), however, this region only adds energy of order $o(1)$.

So, let $m \in X_0$. Since $\theta_m \in [0, \pi]$, we need to treat three different cases:

**Case 1:** $\theta_m \not\in \{0, \alpha, \pi\}$. We proceed in several steps:

**Step 1:** Choice of $a$. We consider the $L^1(\mathbb{R})$ positive function $E: \mathbb{R} \to \mathbb{R}_+$ defined by:

$$E(x_1) := \int_{-1}^{1} |\nabla m(x_1, x_3)|^2 dx_3 \quad \text{for a.e.} \ x_1 \in \mathbb{R}.$$ 

For $\eta \ll 1$, let $b = b(\eta) := \ln \frac{\gamma}{\eta}$ (in fact, any choice $\ln \frac{\gamma}{\eta}$ with $\gamma \in (1, 2)$ would work). We choose

$$a = a(\eta) \in [\frac{b}{2}, b]$$

such that $a$ and $-a$ are Lebesgue points of $E$ and

$$E(a) + E(-a) \leq \int_{\frac{b}{2}}^{b} E(x_1) + E(-x_1) \, dx_1 \leq \frac{2}{b} \int_{\Omega} |\nabla m|^2 \, dx = \frac{C_0}{b}, \quad (41)$$

with $C_0 = 2 \int_{\Omega} |\nabla m|^2 \, dx < \infty$. In particular, the $\dot{H}^{\frac{1}{2}}$-trace of $m$ on the vertical lines $\{\pm a\} \times (-1, 1)$ actually belongs to $H^1$. Since $\bar{m}_2 \mp \sin \theta_m \in H^1(\mathbb{R}_\pm)$ (due to $m_2(\pm \infty, \cdot) = \pm \sin \theta_m$), we also have

$$\bar{m}_2(\pm a) = \pm \sin \theta_m + o(1) \quad \text{as} \ \eta \downarrow 0.$$ 

Recall that Sobolev’s embedding theorem yields existence of $C > 0$ such that

$$\|u\|_{L^\infty} \leq C\|\frac{d}{dx} u\|_{L^2}, \quad \text{for every} \ u \in H^1_0((-1, 1)),$$

together with

$$\|u - \bar{u}\|_{L^\infty} \leq C\|\frac{d}{dx} u\|_{L^2}, \quad \text{for every} \ u \in H^1((-1, 1)).$$

28
Therefore,

\[
\sqrt{\frac{C_0}{b}} \geq \left( \int_{-1}^{1} \sum_{\sigma \in \{\pm 1\}} |\nabla m_1(\sigma a, x_3)|^2 dx_3 \right)^{\frac{1}{2}} \\
\geq \left( \sum_{\sigma \in \{\pm 1\}} \int_{-1}^{1} |\partial_{x_3} m_1(\sigma a, x_3)|^2 + |\partial_{x_2} m_2(\sigma a, x_3)|^2 + |\partial_{x_3} m_3(\sigma a, x_3)|^2 dx_3 \right)^{\frac{1}{2}} \\
\geq C \sum_{\sigma \in \{\pm 1\}} \left( \|m_1(\sigma a, \cdot) - \bar{m}_1(\sigma a)\|_{L^\infty} + \|m_2(\sigma a, \cdot) - \bar{m}_2(\sigma a)\|_{L^\infty} + \|m_3(\sigma a, \cdot)\|_{L^\infty} \right).
\]

(42)

It follows that \(m_1(\pm a, x_3) = \cos \theta_m + o(1), m_3(\pm a, x_3) = o(1)\) and \(m_2(\pm a, x_3) = \bar{m}_2(\pm a) + o(1) = \pm \sin \theta_m + o(1)\) uniformly in \(x_3 \in (-1, 1)\) as \(\eta \downarrow 0\) (since \(b \to \infty\)).

**Step 2:** Definition of \(m_\eta\).

- On \(\Omega_A\), we choose that \(m_\eta(x) = m(x)\) for every \(x \in \Omega_A\).
- On the tail region \(\{|x_1| \geq a + 1\}\), we choose \(m_\eta\) to be the \(S^1\)-valued approximation of a Néel wall with a transition angle that goes from \(-\alpha\) to \(-\theta_m\) (on the left) and from \(\theta_m\) to \(\alpha\) (on the right). More precisely, as in [11], let \(m_\eta : \Omega \setminus (\Omega_A \cup \Omega_I) \to S^1\) depend only on the \(x_1\)-direction and be given by

\[
m_{1,\eta}(x_1, x_3) := \begin{cases} 
\cos \alpha + \frac{\cos \theta_m - \cos \alpha}{\ln \frac{a + 1}{\eta}} \ln \left( \frac{a + 1}{\eta} |x_1| \right), & a + 1 \leq |x_1| \leq \frac{a + 1}{\eta}, \ x_3 \in (-1, 1) \\
\cos \alpha, & a + \frac{1}{\eta} \leq |x_1|, \ x_3 \in (-1, 1), \\
m_{2,\eta}(x_1, x_3) := \text{sgn}(x_1) \sqrt{1 - m_{1,\eta}^2(x_1, x_3)}, & 0 \leq |x_1| \times (-1, 1), \\
m_{3,\eta}(x_1, x_3) := 0,
\end{cases}
\]

on \(\{a + 1 \leq |x_1|\} \times (-1, 1)\).

- On the intermediate region \(\Omega_I\), i.e. for \(a < |x_1| < a + 1\), we define \(m_\eta\) by linear interpolation in \(m_{3,\eta}\) and the phase \(\phi_\eta\) of \((m_{1,\eta}, m_{2,\eta})\) (interpreted as complex number) between \(\Omega_I\) and \(\Omega_A\). For this, we choose \(\eta\) sufficiently small, such that

\[
\pm m_2(\pm a, \cdot) > \frac{\sin \theta_m}{2} > 0 \quad \text{in } (-1, 1).
\]

(43)

Therefore, there exists a unique phase \(\phi_\eta(\pm a, x_3) \in (0, \pi)\) of \((m_1, m_2)(\pm a, x_3) \in \mathbb{R}^2 \simeq \mathbb{C}\) such that

\[
(m_1 + im_2)(\pm a, x_3) = \sqrt{1 - m_3^2(\pm a, x_3)} e^{i \phi_\eta(\pm a, x_3)} \quad \text{for every } x_3 \in (-1, 1).
\]

Observe that the function \(\phi_\eta(\pm a, \cdot)\) depends on \(\eta\) only through \(a\). Recall that \(m_{3,\eta}(\pm(a + 1), \cdot) = 0\) and \((m_{1,\eta} + im_{2,\eta})(\pm(a + 1), \cdot) = e^{i \theta_m}\) so that we fix \(\phi_\eta(\pm(a + 1), \cdot) := \theta_m\) on \((-1, 1)\). By linear interpolation, we then define \(m_\eta : \Omega_I \to \mathbb{S}^2\) and \(\phi_\eta : \Omega_I \to (0, \pi)\)
Indeed, that finally exchange energy estimate.

Step 3: Note that $\mu_1 \cap \mu_2$-traces of $\Omega$ on the intermediate region $\Omega_I$ where we used Lemma 6.

We prove $\int \eta \ll 1$ on the vertical lines $\{\pm a\} \times (-1,1)$ and $\{\pm (a+1)\} \times (-1,1)$ do agree, so that finally $m_\eta \in H^1(\Omega)$, i.e., $m_\eta \in X^\alpha$.

Step 3: Exchange energy estimate. We prove

$$\int_{\Omega} |\nabla m_\eta|^2 dx \leq \int_{\Omega} |\nabla m|^2 dx + o(1).$$

(46)

Indeed,

- on $\Omega_A$, we have that $m_\eta \equiv m$ so that

$$\int_{\Omega_A} |\nabla m_\eta|^2 dx \leq \int_{\Omega} |\nabla m|^2 dx;$$

(47)

- on $\Omega_T$, since $|m_1,\eta| \leq \max(|\cos \theta_m|, \cos \alpha) =: \mu < 1$, we deduce

$$\int_{-1}^{1} \int_{a+1}^{a+\frac{1}{\eta}} |\nabla m_\eta|^2 dx = 2 \int_{a+1}^{a+\frac{1}{\eta}} \frac{|\partial x_1 m_{1,\eta}(x_1)|^2}{1 - m_{1,\eta}(x_1)} dx_1$$

$$\leq 2(\frac{\cos \theta_m - \cos \alpha}{\ln \frac{1}{\eta}})^2 \int_{a+1}^{a+\frac{1}{\eta}} \frac{x_1}{1 - \mu^2} dx_1$$

$$\leq C(\theta_m) \frac{b}{b \ln^2 \frac{1}{\eta}} = o(1) \text{ as } \eta \downarrow 0,$$

(48)

where we used $a + 1 \geq \frac{b}{2}$ in the last inequality;

- on the intermediate region $\Omega_I$, we use the following lemma:

Lemma 6. For $a \leq \pm x_1 \leq a + 1$ and $x_3 \in (-1,1)$, we have

$$\begin{align*}
(i) \quad |\partial x_1 m_{3,\eta}(x)|^2 & \leq m_3^2(\pm a, x_3), \\
(ii) \quad |\partial x_3 m_{3,\eta}(x)|^2 & \leq |\partial x_3 m_3(\pm a, x_3)|^2, \\
(iii) \quad |\partial x_1 (m_{2,\eta})^1(x)|^2 & \leq m_3^2(\pm a, x_3) + |\phi_\eta(\pm a, x_3) - \theta_m|^2, \\
(iv) \quad |\partial x_3 (m_{2,\eta})^1(x)|^2 & \leq 2 |\partial x_3 (m_{2,\eta})^1(\pm a, x_3)|^2.
\end{align*}$$

(49)
Proof. Inequalities (i) and (ii) immediately follow from the definition (44) of $m_{3,\eta}$ on $\Omega_I$.

To prove the remaining inequalities we use the identity $|\partial_x (\rho(x)e^{i\varphi(x)})|^2 = |\partial_x \rho(x)|^2 + |\rho(x)\partial_x \varphi(x)|^2$ for real-valued functions $\rho$ and $\varphi$. Therefore, for (iii), using that $|m_{3,\eta}(x)| \leq |m_3(\pm a, x_3)|$ for $\eta$ sufficiently small (see (42)), we deduce for $x \in \Omega_I$:

$$|\partial_{x_1} (m_{1,\eta} + im_{2,\eta})(x)|^2 = \frac{m_{1,\eta}^2(x)}{1 - m_{3,\eta}^2(x)} |\partial_{x_1} m_{3,\eta}(x)|^2 + \left(1 - m_{3,\eta}^2(x)\right) |\partial_{x_1} \varphi_\eta(x)|^2 \leq 1,$$

$$|\partial_{x_3} (m_{1,\eta} + im_{2,\eta})(x)|^2 \leq \frac{m_{1,\eta}^2(\pm a, x_3)}{1 - m_{3,\eta}^2(\pm a, x_3)} |\partial_{x_3} m_{3,\eta}(\pm a, x_3)|^2 + 2 \left(1 - m_{3,\eta}^2(\pm a, x_3)\right) |\partial_{x_3} \varphi_\eta(\pm a, x_3)|^2 \leq 2 \left(\frac{m_{1,\eta}^2(\pm a, x_3)}{1 - m_{3,\eta}^2(\pm a, x_3)} |\partial_{x_3} m_{3,\eta}(\pm a, x_3)|^2 + \left(1 - m_{3,\eta}^2(\pm a, x_3)\right) |\partial_{x_3} \varphi_\eta(\pm a, x_3)|^2\right) = 2 |\partial_{x_3} (m_1 + im_2)(\pm a, x_3)|^2.$$

Similarly, for (iv), using that $t \mapsto \frac{1}{t^2} - 1$ is increasing on $(0,1)$, we obtain for the $x_3$-derivative of $m_{1,\eta}$ and $m_{2,\eta}$ and $x \in \Omega_I$:

Note that for sufficiently small $\eta$ the function $\varphi_\eta(\pm a, \cdot) \in (0, \pi)$ is bounded away from 0 and $\pi$, such that by Lipschitz continuity of arccos and (42) we have

$$|\varphi_\eta(\pm a, \cdot) - \theta_m|^2 \leq \frac{C(\theta_m)}{b} \text{ on } (-1, 1). \quad (50)$$

Therefore, after integrating (49) over $\Omega_I$, (50), (41) and (42) show that

$$\int_{\Omega_I} |\nabla m_\eta|^2 dx = \int_{|x_3| \leq a} \int_{-1}^1 |\nabla m_\eta|^2 dx_3 dx_1 \leq \frac{C(\theta_m)}{b} = o(1) \text{ as } \eta \downarrow 0, \quad (51)$$

which together with (47) and (48) implies (46).

**Step 4: Stray-field energy estimate.** We will prove that

$$\lambda \ln \frac{1}{\pi} \int_{\mathbb{R}^2} |h(m_\eta)|^2 dx \leq 2\pi \lambda \left(\cos \theta_m - \cos \alpha\right)^2 + o(1). \quad (52)$$

Indeed, we follow the arguments in [11, Proof of Thm. 2(ii)] (see also [12, 14]). First of all, recall that $m_{3,\eta} = 0$ on $\partial \Omega$ and that $\nabla \cdot m_\eta'$ is supported in the compact set $\overline{\Omega_A \cup \Omega_T \cup \Omega_T^\prime}$. 

31
Therefore, the stray field \( h_\eta = -\nabla u_\eta \) with \( u_\eta \in H^1(\mathbb{R}^2) \) satisfies

\[
\int_{\mathbb{R}^2} \nabla u_\eta \cdot \nabla v \, dx = -\int_\Omega \nabla \cdot m'_\eta v \, dx \quad \forall v \in H^1(\mathbb{R}^2),
\]

so that by choosing \( v := u_\eta \), we have:

\[
\int_{\mathbb{R}^2} |\nabla u_\eta|^2 \, dx = -\int_\Omega \nabla \cdot m'_\eta u_\eta \, dx
\]

\[
= -\int_{\Omega_+} \nabla \cdot m'_\eta u_\eta \, dx - \int_{\Omega_T} \nabla \cdot m'_\eta u_\eta \, dx.
\]

(53)

• On \( \Omega_T \), since \( m_{3,\eta} = 0 \) on \( \partial \Omega \) and \( \bar{m}_{1,\eta}(\pm a) = \cos \theta_m \) as well as \( m_{1,\eta}(\pm (a+1), \cdot) = \cos \theta_m \), we have

\[
\int_{(\Omega_T)_+} \nabla \cdot m'_\eta \, dx = \int_{(\partial \Omega_T)_+} m'_\eta \cdot \nu \, dH^1(x) = \bar{m}_{1,\eta}(a+1) - \bar{m}_{1,\eta}(a) = 0
\]

and similarly, \( \int_{(\Omega_T)_-} \nabla \cdot m'_\eta \, dx = 0 \), where \( \nu \) denotes the outer unit normal to \( \Omega_T \) and we use the notation \( (\Omega_T)_+ = \Omega_T \cap \{ x_1 \geq 0 \} \), \( (\Omega_T)_- = \Omega_T \cap \{ x_1 \leq 0 \} \). Therefore we may subtract the averages

\[
\bar{u}_n^+ = \int_{(\Omega_T)_+} u_\eta \, dx \quad \text{and} \quad \bar{u}_n^- = \int_{(\Omega_T)_-} u_\eta \, dx
\]

of \( u_\eta \) over the left and right parts of \( \Omega_T \) such that by (51), Cauchy-Schwarz and Poincaré-Wirtinger’s inequality, we deduce:

\[
\int_{\Omega_T} \nabla \cdot m'_\eta u_\eta \, dx = \int_{(\Omega_T)_-} \nabla \cdot m'_\eta (u_\eta - \bar{u}_n^-) \, dx + \int_{(\Omega_T)_+} \nabla \cdot m'_\eta (u_\eta - \bar{u}_n^+) \, dx
\]

\[
\leq \left( \int_{\Omega_T} |\nabla \cdot m'_\eta|^2 \, dx \right)^{1/2} \left( \int_{(\Omega_T)_-} |u_\eta - \bar{u}_n^-|^2 \, dx \right)^{1/2}
\]

\[
+ \left( \int_{\Omega_T} |\nabla \cdot m'_\eta|^2 \, dx \right)^{1/2} \left( \int_{(\Omega_T)_+} |u_\eta - \bar{u}_n^+|^2 \, dx \right)^{1/2}
\]

\[
\overset{(51)}{\leq} \left( \frac{C}{b} \right)^{1/2} \left( \int_{\mathbb{R}^2} |\nabla u_\eta|^2 \, dx \right)^{1/2}
\]

\[
= \left( C \ln^{-\frac{3}{2}} \eta \right)^{1/2} \left( \int_{\mathbb{R}^2} |\nabla u_\eta|^2 \, dx \right)^{1/2}.
\]

(54)

• On \( \Omega_T \), the stray-field energy can be estimated using the trace characterization (39) and the Cauchy-Schwarz inequality in Fourier space. Indeed, defining \( m_{1,\eta}^{\text{tails}}: \Omega \to \mathbb{R} \)
by setting $m_{1,\eta}^{\text{tails}} = m_{1,\eta}$ on $\Omega \setminus (\Omega_A \cup \Omega_I)$ and $m_{1,\eta}^{\text{tails}} = \cos \theta_m$ on $\Omega_A \cup \Omega_I$, we have

$$
\left| \int_{\Omega_T} \nabla \cdot m' \eta u \eta \, dx \right| = \left| \int_{\Omega_T} \frac{d}{dx_1} m_{1,\eta} \eta \, dx \right|
$$

$$
= \int_{-1}^{1} \int_{\mathbb{R}} \frac{d}{dx_1} m_{1,\eta} \eta \, dx_1 \, dx_3
$$

$$
\leq \int_{-1}^{1} \int_{\mathbb{R}} |k_1| |\mathcal{F}_{x_1} m_{1,\eta}^{\text{tails}}(k_1)| |\mathcal{F}_{x_1} u_\eta(k_1, x_3)| \, dk_1 \, dx_3
$$

$$
\leq \int_{-1}^{1} \left( \int_{\mathbb{R}} |k_1| |\mathcal{F}_{x_1} m_{1,\eta}^{\text{tails}}(k_1)|^2 \, dk_1 \int_{\mathbb{R}} |k_1| |\mathcal{F}_{x_1} u_\eta(k_1, x_3)|^2 \, dk_1 \right)^{\frac{1}{2}} \, dx_3
$$

$$
\leq \left( \int_{\mathbb{R}^2} |\nabla u_\eta|^2 \, dx \right)^{\frac{1}{2}} \left( 2 \int_{\mathbb{R}} \left| \frac{d}{dx_1} m_{1,\eta}^{\text{tails}} \right|^2 \, dx_1 \right)^{\frac{1}{2}}. \tag{55}
$$

By considering the radial extension $M_{1,\eta}(x) = m_{1,\eta}^{\text{tails}}(|x|)$ of $m_{1,\eta}^{\text{tails}}$ on $\mathbb{R} \times \mathbb{R}_+$, which is possible since $m_{1,\eta}^{\text{tails}}$ is even, and using polar coordinates we then can estimate

$$
\int_{\mathbb{R}} \left| \frac{d}{dx_1} m_{1,\eta}^{\text{tails}} \right|^2 \, dx_1 \overset{(39)}{\leq} \int_{\mathbb{R} \times \mathbb{R}_+} |\nabla M_{1,\eta}|^2 \, dx
$$

$$
\quad \leq \pi \int_{\alpha+1}^{\infty} \left| \frac{d}{dx_1} m_{1,\eta}^{\text{tails}} \right|^2 \, x_1 \, dx_1
$$

$$
\quad = \pi \frac{(\cos \theta_m - \cos \alpha)^2}{\ln \frac{1}{\eta}} \int_{\alpha+1}^{\infty} \frac{1}{x_1} \, dx_1
$$

$$
\quad = \pi \frac{(\cos \theta_m - \cos \alpha)^2}{\ln \frac{1}{\eta}}.
$$

Collecting (53), (54), and (55), it follows that

$$
\lambda \ln \frac{1}{\eta} \int_{\Omega} |\nabla u_\eta|^2 \, dx \leq \lambda \ln \frac{1}{\eta} \left( C \ln^{-\frac{3}{4}} \frac{1}{\eta} + \left( 2 \pi \frac{(\cos \theta_m - \cos \alpha)^2}{\ln \frac{1}{\eta}} \right)^{\frac{1}{2}} \right)^2
$$

$$
\leq 2 \pi \lambda (\cos \theta_m - \cos \alpha)^2 + C \ln^{-\frac{3}{4}} \frac{1}{\eta},
$$

i.e. (52).\footnote{In fact, this motivates the choice $b = \ln^{-\frac{1}{4}} \frac{1}{\eta}$ with $\gamma > 1$.}

**Step 5: Anisotropy energy estimate.** Finally, we prove

$$
\eta \int_{\Omega} (m_{1,\eta} - \cos \alpha)^2 + m_{1,\eta}^2 \, dx = o(1). \tag{56}
$$
Indeed, since \( a \sim b = \ln^\frac{3}{2} \frac{1}{\eta} \), on \( \Omega_A \cup \Omega_I \) we have
\[
\eta \int_{-a+1}^{a+1} \int_{-1}^{1} (m_{1,\eta} - \cos \alpha)^2 + m_{3,\eta}^2 \, dx \, dx_1 \leq C \eta \ln^\frac{3}{2} \frac{1}{\eta} = o(1),
\]
and on \( \Omega_T \), \( m_{3,\eta} = 0 \) so that\(^{13}\)
\[
\eta \int_{\Omega_T} (m_{1,\eta} - \cos \alpha)^2 + m_{3,\eta}^2 \, dx
= 4\eta \frac{(\cos \theta_m - \cos \alpha)^2}{\ln^\frac{2}{\eta}} \int_{a+1}^{a+1} \ln^2 (\frac{a+1}{\eta x_1}) \, dx_1
\leq C \frac{\eta^2}{\eta} \int_\eta^{\eta a+1} \ln^2 y \, dy
\leq C \ln^{-\frac{2}{\eta}} \frac{1}{\eta} = o(1).
\]
Moreover, on \( \Omega \setminus (\Omega_A \cup \Omega_I \cup \Omega_T) \) we have \( (m_{1,\eta} - \cos \alpha)^2 + m_{3,\eta}^2 = 0 \) so that (56) holds.

**Step 6: Conclusion.** Combining (46), (52) and (56), it follows that
\[
E_\eta(m_\eta) = \int_{\Omega} |\nabla m_\eta|^2 \, dx + \lambda \ln \frac{1}{\eta} \int_{\mathbb{R}^2} |h(m_\eta)|^2 \, dx + \eta \int_{\Omega} (m_{1,\eta} - \cos \alpha)^2 + m_{3,\eta}^2 \, dx
\leq \int_{\Omega} |\nabla m|^2 \, dx + 2\pi \lambda \,(\cos \theta_m - \cos \alpha)^2 + o(1) = E_0(m) + o(1),
\]
which is (13). Finally, let us prove that \( m_\eta \to m \) in \( \dot{H}^1(\Omega) \). First, observe that by construction, \( m_\eta \equiv m \) on \( \Omega_A \). Therefore, since \( \cup_{\eta>0} \Omega_A = \Omega, m_\eta \to m \) in \( L^2_{\text{loc}}(\Omega) \). Moreover, (46) implies that \( \{m_\eta\}_{\eta>0} \) is uniformly bounded in \( \dot{H}^1(\Omega) \), so that \( m_\eta \to m \) in \( \dot{H}^1(\Omega) \). By weak lower-semicontinuity of \( \|\cdot\|_{L^2(\Omega)} \) and (46), one obtains \( \|\nabla m_\eta\|_{L^2(\Omega)} \to \|\nabla m\|_{L^2(\Omega)} \) and concludes that \( m_\eta \to m \) in \( \dot{H}^1(\Omega) \).

**Case 2: \( \theta_m \in \{0, \pi\} \).** By Remark 1, \( m \) is constant, such that its exchange energy does not contribute to \( E_0(m) \). Thus, we have to construct a sequence \( m_\eta \) of asymptotically vanishing exchange energy, whose stray-field and anisotropy energy converge to \( 2\pi \lambda \,(\cos \theta_m - \cos \alpha)^2 \). The function \( m_\eta \) from Case 1 is a good candidate for the second property. However, if \( \theta_m \in \{0, \pi\} \), it does not belong to \( H^1(\Omega) \), since then \( 1 - m_{1,\eta}^2 \) behaves linearly w.r.t. the distance to the set \( \{m_{1,\eta}^2 = 1\} \) and (48) fails. Therefore, we are obliged to construct a transition region between the two tails where this behavior is corrected.

With these considerations, we define \( m_\eta: \Omega \to S^1 \) by
\[
m_{1,\eta}(x_1, x_3) := \begin{cases} 
\cos \theta_m - \frac{1}{\eta} (\cos \theta_m - \cos \alpha) \frac{\ln^2 x_1^2}{\ln \frac{1}{\eta}}, & |x_1| \leq 2, \\
\cos \alpha + (\cos \theta_m - \cos \alpha) \frac{\ln \frac{1}{\eta}}{\ln \frac{1}{\eta}}, & 2 \leq |x_1| \leq \frac{1}{\eta}, \\
\cos \alpha, & \frac{1}{\eta} \leq |x_1|, 
\end{cases}
\]
\(^{13}\)Note that here it is important to have \( b = \ln^\frac{3}{2} \frac{1}{\gamma} \) with \( \gamma < 2 \).
and again
\[
m_{2,\eta}(x_1, x_3) := \text{sgn}(x_1) \sqrt{1 - m_{1,\eta}^2(x_1, x_3)},
m_{3,\eta}(x_1, x_3) := 0.
\]

Admissibility in \(X^\alpha\) is obvious and one can then show, using the methods given above, that
\[
\int_\Omega |\nabla m_\eta|^2 dx \leq C \ln^{-\frac{1}{\eta}},
\]
\[
\lambda \ln \frac{1}{\eta} \int_{\mathbb{R}^2} |\nabla u_\eta|^2 dx \leq 2\pi \lambda (\cos \theta_m - \cos \alpha)^2 + C \ln^{-\frac{1}{\eta}},
\]
\[
\eta \int_\Omega (m_1,\eta - \cos \alpha)^2 + m_3,\eta dx \leq C \ln^{-\frac{1}{\eta}}.
\]

The strong convergence \(m_\eta \to m\) in \(H^1(\Omega)\) also follows as in Step 6 of Case 1 by noting that the constructed transition layer \(m_\eta\) has the property \(m_\eta \to m = (\cos \theta_m, \pm \sin \theta_m, 0)\) a.e. in \(\Omega\).

**Case 3:** \(\theta_m = \alpha\). Since \(m\) already has the correct boundary values, we can simply choose:
\[
m_\eta := m.
\]

Admissibility of \(m_\eta\) in \(X^\alpha\) is clear and we can estimate:
\[
\int_\Omega |\nabla m_\eta|^2 dx = \int_\Omega |\nabla m|^2 dx,
\]
\[
\lambda \ln \frac{1}{\eta} \int_{\mathbb{R}^2} |h(m_\eta)|^2 dx = 0 = 2\pi \lambda (\cos \alpha - \cos \alpha)^2,
\]
\[
\eta \int_\Omega (m_1,\eta - \cos \alpha)^2 + m_3,\eta dx = o(1),
\]

since \(m(\pm \infty, \cdot) = (\cos \alpha, \pm \sin \alpha, 0)\). \(\Box\)

**Proof of Corollary 1.** The first equality in (14) is a direct consequence of the concept of \(\Gamma\)-convergence. Indeed, we know by Theorem 3 that there exists a minimizer \(m_\eta \in X^\alpha\) of \(E_\eta\) for every \(0 < \eta < 1\). By Proposition 1, up to a subsequence and translation in \(x_1\)-direction, we have that \(m_\eta \rightharpoonup m\) in \(H^1(\Omega)\) for some \(m \in X_0\) so that Theorem 1 implies
\[
\liminf_{\eta \downarrow 0} \min_{X^\alpha} E_\eta = \liminf_{\eta \downarrow 0} E_\eta(m_\eta) \geq E_0(m) \geq \min_{X_0} E_0.
\]

On the other hand, Theorem 3 also implies existence of a minimizer \(m \in X_0\) of \(E_0\). By Theorem 2, there exists a family \((\tilde{m}_\eta)_{\eta \downarrow 0} \subset X^\alpha\) such that
\[
\min_{X_0} E_0 = E_0(m) \geq \limsup_{\eta \downarrow 0} E_\eta(\tilde{m}_\eta) \geq \limsup_{\eta \downarrow 0} \min_{X^\alpha} E_\eta,
\]

35
Therefore, \( \min_{X^0} E_\eta \to \min_{X_0} E_0 \) as \( \eta \downarrow 0 \). For the second equality in (14), note that by Theorem 3 one has

\[
\min_{X_0} E_0 = \min_{\theta \in [0, \pi]} \left( E_{\text{asym}}(\theta) + \lambda E_{\text{sym}}(\alpha - \theta) \right).
\]

By Lemma 4, the minimum of the RHS is indeed attained. It remains to show that it is achieved for angles \( \theta \in [0, \frac{\pi}{2}] \). Indeed, let \( \theta \in [0, \pi] \) be the minimizer of the above RHS and \( m \in X_0 \) with \( \theta_m = \theta \) be the minimizer of \( E_{\text{asym}}(\theta) \). If \( \theta \in (\frac{\pi}{2}, \pi] \), then one considers \( \tilde{m} \in X_0 \) given by \( \tilde{m}_1 \equiv -m' \) and \( \tilde{m}_2 \equiv m_2 \), so that \( \theta_m = \pi - \theta_m \in [0, \frac{\pi}{2}] \). Then \( \tilde{m} \) and \( m \) have the same exchange energy (i.e., \( E_{\text{asym}}(\theta_m) = E_{\text{asym}}(\theta_m) \)) and \( E_{\text{sym}}(\alpha - \theta_m) \leq E_{\text{sym}}(\alpha - \theta_m) \) which proves (14). Observe that the last inequality is strict whenever \( \alpha \in (0, \frac{\pi}{2}) \), so that for such angles \( \alpha \) the minimal value of \( E_0 \) is achieved only for angles \( \theta \in [0, \frac{\pi}{2}] \).

Let us now prove the relative compactness in the strong \( \dot{H}^1 \)-topology of minimizing families \( \{m_\eta\}_{\eta \downarrow 0} \subset X^0 \) of \( E_\eta \), i.e., which satisfy \( E_\eta(m_\eta) \to \min_{X_0} E_0 \). By Proposition 1, up to a subsequence and translations in \( x_1 \)-direction, we may assume that \( m_\eta \to m \) in \( H^1(\Omega) \) for some \( m \in X_0 \) so that Theorem 1 implies \(^14\)

\[
\min_{X_0} E_0 = \lim_{\eta \downarrow 0} E_\eta(m_\eta) \\
\geq \limsup_{\eta \downarrow 0} \int_\Omega |\nabla m_\eta|^2 dx + \liminf_{\eta \downarrow 0} \left( \lambda \ln \frac{1}{\eta} \int_\mathbb{R}^2 |h(m_\eta)|^2 dx + \eta \int_\Omega (m_1, \eta - \cos \alpha)^2 dx \right) \\
\geq E_{\text{asym}}(\theta_m) + \lambda E_{\text{sym}}(\alpha - \theta_m) \geq \min_{X_0} E_0.
\]

Therefore, all above inequalities become equalities, in particular, \( \lim_{\eta \downarrow 0} \int_\Omega |\nabla m_\eta|^2 dx = \int_\Omega |\nabla m|^2 dx \). Hence, one has \( m_\eta \to m \) in \( H^1(\Omega) \), i.e. up to the subsequence taken in Proposition 1 and translations the entire family \( m_\eta \) converges strongly to \( m \) in \( H^1(\Omega) \) where \( m \) is a minimizer of \( E_0 \).

\( \square \)

Appendix

A  Construction of an asymmetric-Bloch type wall of arbitrary wall angle \( \theta \in (0, \frac{\pi}{2}] \)

In this section we construct a stray-field free domain wall for any given angle \( \theta \in (0, \frac{\pi}{2}] \). In particular, this shows that the set \( X_0 \cap X^0 \) is non-empty, and we may apply the direct method in the calculus of variations to deduce existence of minimizers of \( E_{\text{asym}} \) (cf. Theorem 3).

The construction we present here is of asymmetric Bloch-wall type in the following sense: The trace of \( m \in H^1(\Omega, \mathbb{S}^2) \) on the boundary \( \text{Bdry} := \partial \Omega \cup \left( \{\pm \infty\} \times [-1, 1] \right) \cong \mathbb{S}^1 \) (see (16))

\(^{14}\)We use that \( \limsup (a_n + b_n) \geq \limsup a_n + \liminf b_n \) for two bounded sequences \( (a_n) \) and \( (b_n) \).
has a non-zero topological degree. In fact, due to \( m_3 = 0 \) on \( \partial \Omega \) as well as \( m_3(\pm \infty, \cdot) = 0 \) (so, \((m_1, m_2) : Bdry \rightarrow S^1\)), one obtains (by the homeomorphism (16)) a map \( \tilde{m} \in H^1(S^1, S^1) \) to which a topological degree can be associated (see, e.g., [4]).

**Remark 5.** (i) Asymmetric Bloch walls as well as the configuration we are about to construct do have a non-zero topological degree (e.g. \( \pm 1 \)) on \( \partial \Omega \). We make the following observation (see Lemma 2): the non-vanishing topological degree of \((m_1, m_2) : Bdry \rightarrow S^1\) nucleates at least one vortex singularity of \((m_1, m_3)\) (carrying a non-zero topological degree) as illustrated in Figure 3.

(ii) Note that for the angle \( \theta = 0 \), by Remark 1, one has that \( m \in X_0 \) if and only if \( m \in \{ \pm e_1 \} \), so that \( m \) has degree zero on \( \partial \Omega \); thus, no asymmetric-Bloch type wall exists in this case.

(iii) An asymmetric-Néel type configuration \( \tilde{m} \in X_0 \cap X_\theta \), i.e. with deg \( \tilde{m} = 0 \), can be obtained from any \( m \in X_0 \cap X_\theta \) using even reflection in \((m_1, m_2)\) and odd reflection in \( m_3 \) across one of the components of \( \partial \Omega \) together with a rescaling in \( x \) so that \( \tilde{m} \) is defined on \( \Omega \). However, starting with \( m \in L^\theta \) (introduced at Section 1.3), the reflected configuration has at least two vortices in \((m_1, m_3)\), so that it cannot have minimal energy. In [7], we construct an asymptotically energy minimizing configuration of asymmetric-Néel type for small angles.

The degree argument shows that we cannot expect a homotopy between asymmetric Néel and Bloch wall in the class of stray-field free walls. Hence, it is unclear how the nevertheless expected transition from asymmetric Néel to Bloch wall actually takes place.

**Proposition 3.** Given \( \theta \in (0, \frac{\pi}{2}] \), there exists a map \( m : \Omega \rightarrow S^2 \) with the following properties:

- \( m \in \dot{H}^1(\Omega) \),
- \( m(x_1, \cdot) = m_0^\pm \) for all \( |x_1| \) sufficiently large,
- \( \nabla \cdot m' = 0 \) in \( \Omega \) and \( m_3 = 0 \) on \( \partial \Omega \),
- \( \text{deg}(m|_{\partial \Omega}) = -1 \).

**Proof.** To construct \( m \), we will search for a stream function \( \psi : \mathbb{R}^2 \rightarrow \mathbb{R} \) with the following properties:

(i) \( \psi \in C^3(\mathbb{R}^2) \) with \( |\nabla \psi| \leq 1 \) in \( \mathbb{R}^2 \), \(^{15}\)

(ii) \( \psi(x) = -(x_3 + 1) \cos \theta \) for all \( |x| \) sufficiently large,

(iii) \( \psi(\cdot, -1) = 0 \) and \( \psi(\cdot, 1) = -2 \cos \theta \) in \( \mathbb{R} \),

(iv) there exists a continuous curve \( \gamma \), connecting the upper and lower components \( \mathbb{R} \times \{ +1 \} \) and \( \mathbb{R} \times \{ -1 \} \) of \( \partial \Omega \), on which \( |\nabla \psi| = 1 \).

\(^{15}\)In fact, we will construct a smooth function \( \psi \).
\[ \gamma - 2\left(1 - \cos \theta\right) \geq 1 - \cos \theta \geq 1 - \frac{1}{2} \]

Figure 7: Sketch of the level lines of a stream function of an asymmetric domain wall of Bloch type.

\[ \frac{-2(1 - \cos \theta)}{2 \cos \theta} \leq \gamma \leq \frac{2(1 - \cos \theta)}{2 \cos \theta} \]

Figure 8: Enlargement of the area around the vortex, cf. Figure 7.

We then define \( m \) according to

\[
\begin{align*}
    m' &= \nabla \psi, \quad m_2(x) := \begin{cases} 
        -\sqrt{1 - |\nabla \psi(x)|^2}, & \text{if } x \text{ is to the left of } \gamma, \\
        \sqrt{1 - |\nabla \psi(x)|^2}, & \text{if } x \text{ is to the right of } \gamma.
    \end{cases}
\end{align*}
\]

(57)

Figure 9: Sketch of vortex function \( s \) with ellipsoid level sets in the inner part.

**Step 1:** *Construction in the inner part around the vortex.* As a first step in the construction of \( \psi \) we implicitly define a function \( s \in C^\infty(Q) \),

\[
    Q = ([-1, 1] \times \mathbb{R}) \setminus \{(0, 0)\},
\]

by specifying its level sets (cf. Figure 9). Later, we will define \( \psi \) by rescaling, shifting and
smoothing the function $1 - s$. Consider

$$f: Q \times (0, \infty) \to \mathbb{R}, \quad f(\hat{x}, s) := \begin{cases} \left(\frac{\hat{x}_3}{s}\right)^2 - 1, & \text{if } s \geq \frac{1}{2}, \hat{x} \in Q, \\ \left(\frac{s}{\hat{x}_3}\right)^2 \left(\frac{\hat{x}_1}{\hat{x}_3}\right)^2 + \left(\frac{\hat{x}_2}{\hat{x}_3}\right)^2 - 1, & \text{if } 0 < s < \frac{1}{2}, \hat{x} \in Q, \end{cases}$$

where $t: (0, \frac{1}{2}) \to \mathbb{R}$ is a smooth function that satisfies the structural condition

$$t(s) = s \quad \text{if } s \in [0, \frac{1}{4}], \quad \frac{d^2}{ds^2} t \geq 0 \quad \text{on } (0, \frac{1}{2}),$$

and such that $\frac{1}{t(s)}$ vanishes to infinite order at $s = \frac{1}{2}$, e.g.

$$t(s) = e^{\frac{1}{2-s}} \quad \text{if } s \in \left[\frac{3}{8}, \frac{1}{2}\right].$$

We note that the latter implies that $f$ is smooth across $s = \frac{1}{2}$ and thus in the whole domain $Q \times (0, \infty)$.

**Claim:** For every $\hat{x} \in Q$ there exists a unique solution $s = s(\hat{x})$ of $f(\hat{x}, s) = 0$.

We first argue that the solution is unique: Indeed, because of (58) we have in particular $\frac{d^2}{ds^2} t(s) \geq 1$ so that $\partial_s f(\hat{x}, s) < 0$ for all $(\hat{x}, s) \in Q \times (0, \infty)$, provided we are not in the case of $s \geq \frac{1}{4}$ and $\hat{x}_3 = 0$. This case however is not relevant for uniqueness since then $f(\hat{x}, s) \equiv -1$.

It follows from the explicit form of $f$ that

$$s(\hat{x}) = \begin{cases} |\hat{x}|, & \text{for } |\hat{x}| \leq \frac{1}{4}, \\ |\hat{x}_3|, & \text{for } |\hat{x}_3| \geq \frac{1}{2}, \end{cases}$$

is a solution.

Hence, it remains to show existence of a solution for $|\hat{x}_3| < \frac{1}{4}$ but $|\hat{x}| > \frac{1}{4}$. Indeed, $|\hat{x}_3| < \frac{1}{2}$ implies $f(\hat{x}, \frac{1}{2}) < 0$ and $|\hat{x}| > \frac{1}{4}$ yields $f(\hat{x}, \frac{1}{2}) > 0$. Thus, the existence of a solution $s = s(\hat{x}) \in (\frac{1}{4}, \frac{1}{2})$ of $f(\hat{x}, s) = 0$ follows from the intermediate value theorem.
The implicit function theorem yields smoothness of \( s : Q \to (0, \infty) \), with
\[
\hat{\nabla} s(\dot{x}) = -\nabla f(\dot{x}, s(\dot{x})) = \frac{1}{x^2} \frac{\partial}{\partial x} \frac{\hat{x}}{t(s)} + \frac{\hat{x}^2}{x^2}, \quad \text{if } |\dot{x}| \leq \frac{1}{2},
\] (59)
and \( \hat{\nabla} \hat{s}(\dot{x}) = \pm e_3 \) if \( \pm \dot{x}_3 \geq \frac{1}{2} \). Note that
\[
|\hat{\nabla} s(\dot{x})|^2 = \frac{\left(\frac{\hat{x}_1}{t(s)}\right)^2 + \frac{\hat{x}_2}{x} \frac{\hat{x}_1}{t(s)} + \frac{\hat{x}_2^2}{x^2}}{t(s)} \leq \frac{\frac{1}{x^2} \left(\frac{\hat{x}_1}{t(s)}\right)^2 + \frac{\hat{x}_2}{x} \frac{\hat{x}_1}{t(s)} + \frac{\hat{x}_2^2}{x^2}}{t(s)} = 1 \quad \text{if } |\dot{x}| \leq \frac{1}{2},
\]
since (58) yields \( \frac{1}{t(s)} \leq \frac{1}{2} \) and \( \frac{dt(s)}{ds} \geq \frac{1}{2} \) whenever \( s \in (0, \frac{1}{2}) \).

Let us finally remark that the curve
\[
\dot{\gamma} \subset \{0\} \times \{|x_3| \geq \frac{1}{2}\} \cup (B(0, \frac{1}{4}) \setminus B(0, \frac{1}{16}))
\] (60)
which is indicated in Figure 9, has the property
\[
|\hat{\nabla} s| = 1 \quad \text{on } \dot{\gamma}.
\]

**Step 2: Regularization of the vortex at } \dot{x} = 0\). In this step, we define a function \( \hat{\psi}_1 \) on \([-1, 1] \times \mathbb{R}\) that – up to rescaling and recentering – already coincides with the final \( \psi \) close to \( \{x_1 = 0\} \). The subsequent steps 3-6 modify \( \hat{\psi}_1 \) for large \( \dot{x} \in \mathbb{R}^2 \) to achieve the boundary conditions for \( |x_1| \to \infty \) and to make Lemma 7 applicable.

In principle, we would like to set \( \hat{\psi}_1 = 1 - s \), but since \( s \) is not smooth in \( \dot{x} = 0 \) this would generate a vortex-type point-singularity at \( \dot{x} = 0 \) for \( \nabla \hat{\psi}_1 \). Instead, let \( \rho : [0, \infty) \to \mathbb{R} \) be a smooth function that satisfies
\[
\rho(s) = 1 - s \quad \text{if } s \geq \frac{1}{16}, \quad -1 \leq \frac{d^n \hat{\rho}}{ds^n}(s) \leq 0 \quad \text{if } s \geq 0, \quad \frac{d^n \rho}{ds^n}(0) = 0 \quad \text{for all integers } n > 0.
\]

Then the function
\[
\hat{\psi}_1(\dot{x}) := \rho(s(\dot{x})), \quad \dot{x} \in Q,
\]
is smooth, satisfies \( |\hat{\nabla} \hat{\psi}_1| = |\frac{d}{ds} \rho| |\hat{\nabla} s| \leq 1 \) and can be extended to a smooth function \( \hat{\psi}_1 \) on \([-1, 1] \times \mathbb{R}\) by setting \( \hat{\psi}_1(\dot{x} = 0) := \rho(s = 0) \). The regularity of \( \hat{\psi}_1 \) around \( \dot{x} = 0 \) is due to \( s(\dot{x}) = |\dot{x}| \) for \( |\dot{x}| \leq \frac{1}{2} \) and \( \frac{d^n \rho}{ds^n}(0) = 0 \) for all \( n > 0 \).

Note that by definition of \( \rho \) and \( s \) we still have
\[
|\hat{\nabla} \hat{\psi}_1| = 1 \quad \text{on } \dot{\gamma},
\]
for \( \dot{\gamma} \) as in (60).

**Step 3: Extending } \hat{\psi}_1 \text{ to } \mathbb{R}^2\). Here, we use \( \hat{\psi}_1 \) (defined on \([-1, 1] \times \mathbb{R}\)) to define a smooth function \( \hat{\psi}_2 \) on \( \mathbb{R}^2 \) with the properties
\[
\partial_{\dot{x}_1} \hat{\psi}_2 = 0 \quad \text{if } |\dot{x}_1| \geq 2, \quad |\hat{\nabla} \hat{\psi}_2| \leq 1 \text{ on } \mathbb{R}^2, \quad |\hat{\nabla} \hat{\psi}_2| = 1 \text{ on } \dot{\gamma}.
\] (61)
Let $\varphi: \mathbb{R} \rightarrow [-1, 1]$ be a smooth odd non-linear change of variables (cf. Figure 11) with
\[
\varphi(s) = s \text{ on } (0, \frac{1}{4}), \quad \varphi(s) = 1 \text{ if } s \geq 2, \quad 0 < \frac{d}{ds}\varphi(s) \leq 1 \text{ on } (0, 2).
\]
Then we let
\[
\hat{\psi}_2(\hat{x}) := \hat{\psi}_1(\varphi(\hat{x}_1), \hat{x}_2) \quad \text{for } \hat{x}_1 \in \mathbb{R}^2,
\]
such that the properties (61) are easily verified.

**Step 4:** Matching the boundary conditions on $\partial \Omega$. In this step, we rescale and recenter $\hat{\psi}_2$ according to Figure 7 to achieve the boundary conditions $0$ and $-2 \cos \theta$ on the lower and upper components of $\partial \Omega$, i.e. (iii).

More precisely, we want to obtain (63) below. Since $\hat{\psi}_2(\hat{x}) = 1 - |\hat{x}_3|$ for $|\hat{x}_3| \geq \frac{1}{2}$, we place the center of the “regularized vortex” $\hat{x} = 0$ of $\hat{\psi}_2$ at $x_\theta = (0, -\cos \theta)$, and thereby define the smooth function:
\[
\psi_2(x) := (1 - \cos \theta) \hat{\psi}_2(\hat{x}) \quad \text{for } x \in \mathbb{R}^2,
\]
where $\hat{x}$ is related to $x$ via
\[
x = x_\theta + (1 - \cos \theta)\hat{x}. \quad (62)
\]
Then
\[
\psi_2(x) = 1 - \cos \theta - |x_3 + \cos \theta| \quad \text{on } \{ |x_3 + \cos \theta| \geq \frac{1-\cos \theta}{2} \} \supset \partial \Omega, \quad (63)
\]
such that the boundary conditions hold. Moreover, we have $|\nabla \psi_2| \leq 1$ in $\mathbb{R}^2$ as well as $|\nabla \psi_2| = 1$ on the curve $\gamma$ that $\hat{\gamma}$ induces via the change of variables (62), cf. Figure 7.

Note that $\psi_2$ only depends on $x_3$ for $|x_3| \geq 2(1 - \cos \theta)$. However, (ii) does not yet hold.

**Step 5:** Controlling the behavior for $|x_3| \gg 1$. To allow for an application of Lemma 7 we want to obtain (ii), in particular bounded second derivatives of $f = 1 - |\nabla \psi|^2$. To this end, we will first interpolate $\psi_2$ in $x_3$ with the boundary data
\[
\psi_{\text{out}} := -(x_3 + 1) \cos \theta
\]
for $|x_3| \gg 1$. In Step 6, we will then interpolate with $\psi_{\text{out}}$ in $x_1$.

We proceed in two steps: First, we employ a regularized $\max(\hat{\ell}, t)$-function to modify $\psi_2$ outside of $\Omega$ to make sure that the slope of $\psi_2$ agrees with that of $\psi_{\text{out}}$ for large $|x_3|$. Then,
Figure 12: Sketch of the functions $\psi_2(x_1, \cdot)$ (for $|x_1|$ large, fixed) and $\psi_{\text{out}}$, as well as their interpolant $\psi_{\text{in}}$.

since $|\partial_{x_3} \psi_{\text{out}}| = \cos \theta < 1$, we can use interpolation with a slowly varying cut-off function to define a new function $\psi_{\text{in}}$ that coincides with $\psi_{\text{out}}$ for $|x_3| \gg 1$ and still satisfies $|\nabla \psi_{\text{in}}| \leq 1$, cf. Figure 12.

Let $\eta: \mathbb{R} \to [0, 1]$ be a smooth, increasing cut-off function with $\eta \equiv 0$ on $\mathbb{R}_-$, $\eta \equiv 1$ on $[1, \infty)$, and $\|\partial \eta\|_{\infty} < \infty$. To regularize

$$\max(\tilde{t}, t) = \tilde{t} + \max(0, t - \tilde{t}) = \tilde{t} + \int_0^{t-\tilde{t}} 1_{[0,\infty)}(s) \, ds$$

we replace $1_{[0,\infty)}$ by $\eta$, i.e. we define a smooth $h: \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ via

$$h(\tilde{t}, t) := \tilde{t} + \int_0^{t-\tilde{t}} \eta(s) \, ds.$$ (64)

Observe that

$$h(\tilde{t}, t) = \tilde{t} \text{ if } \tilde{t} \geq t, \quad \text{and} \quad h(\tilde{t}, t) = \int_0^1 \eta(s) \, ds - 1 + t, \text{ if } t \geq \tilde{t} + 1.$$ (65)

Moreover, $\partial \tilde{t} h(\tilde{t}, t) = 1 - \eta(t - \tilde{t})$ and $\partial t h(\tilde{t}, t) = \eta(t - \tilde{t})$.

Hence, the function $\psi_3: \mathbb{R}^2 \to \mathbb{R}$ given by

$$\psi_3(x) := \begin{cases} 
\psi_2(x), & \text{for } x \in \Omega, \\
h(\psi_2(x), \psi_{\text{out}}(x) - 1), & \text{otherwise}, 
\end{cases}$$

is smooth and satisfies

$$\psi_3 \equiv \psi_2 \text{ on } \Omega, \quad \psi_3 - \psi_{\text{out}} = \int_0^1 \eta \, ds - 2 \text{ if } |x_3| \geq 1 + \frac{2}{1 - \cos \theta} =: M_\theta, \quad (65)$$

$$|\nabla \psi_3| \leq 1 \text{ on } \Omega, \quad \partial_{x_3} \psi_3 = 0 \text{ for } |x_3| \geq 2,$$

$$|\nabla \psi_3| \leq (1 - \eta(\psi_{\text{out}} - 1 - \psi_2)) |\nabla \psi_2| + \eta(\psi_{\text{out}} - 1 - \psi_2) |\nabla \psi_{\text{out}}| \leq 1 \text{ on } \mathbb{R}^2 \setminus \Omega.$$
It remains to interpolate $\psi_3$ and $\psi_{out}$: For $L \geq M_\theta + 1$, consider the slowly varying cut-off function $\eta_L : \mathbb{R}_+ \to [0, 1]$ given by

$$\eta_L(t) := \eta^2\left(\frac{t-M_\theta}{L-M_\theta}\right).$$

Then

$$\eta_L(t) = 0 \text{ if } t \leq 2, \quad \eta_L(t) = 1 \text{ if } t \geq L, \quad \left(\frac{d}{dt}\eta_L\right)^2 \leq \frac{C(\theta)}{L^2} \eta_L \leq \frac{C(\theta)}{L^2} \text{ on } \mathbb{R}_+, \quad (67)$$

and we define the smooth function $\psi_{in} : \mathbb{R}^2 \to \mathbb{R}$ by

$$\psi_{in}(x) := \eta_L(|x_3|)\psi_{out}(x) + (1 - \eta_L(|x_3|))\psi_3(x),$$

There exists $L(\theta)$ such that for any $L \geq L(\theta)$ we have $|\nabla\psi_{in}| \leq 1$ on $\mathbb{R}^2$: Note that $|\nabla\psi_{in}| = |\nabla\psi_3| \leq 1$ on $\{|x_3| \leq M_\theta\}$, while on $\{|x_3| \geq M_\theta\}$ we have $\psi_{in} \equiv \psi_{out} - (2 - \int_0^1 \eta ds)(1 - \eta_L(|x_3|))$, such that due to $\nabla\psi_{out} = (0, -\cos \theta)$

$$|\nabla\psi_{in}| \leq |\nabla\psi_{out}| \leq \cos \theta + \frac{C}{L} \leq 1 \text{ for } L \text{ sufficiently large.}$$

Moreover, $\partial_{x_1}\psi_{in} = 0 \text{ for } |x_1| \geq 2(1 - \cos \theta)$.

**Step 6: Interpolation with the boundary conditions at } x_1 = \pm \infty. In order to obtain (ii) it now remains to interpolate $\psi_{in}$ with the boundary data $\psi_{out}$ for $|x_1| \gg 1$. For this, we again consider the cut-off function $\eta_L : \mathbb{R}_+ \to [0, 1]$ with properties (67) and define the desired smooth $\psi : \mathbb{R}^2 \to \mathbb{R}$ by

$$\psi(x) := \eta_L(|x_1|)\psi_{out}(x) + (1 - \eta_L(|x_1|))\psi_{in}(x).$$

Clearly, $\psi$ satisfies the boundary conditions on $\partial\Omega$ as well as $\psi = \psi_{out}$ for $|x| \gg 1$. In the core region $\{|x_1| \leq M_\theta\} \cap \Omega$ we have $\psi = \psi_{in} = \psi_3 = \psi_2$ and therefore $|\nabla\psi| = 1$ on the curve $\gamma$ defined in Step 4. Moreover, $|\nabla\psi| \leq 1$ on $\{|x_1| \leq M_\theta\} \cup \{|x_1| \geq L\}$.

For sufficiently large $L \geq L(\theta)$ we can also assert $|\nabla\psi| \leq 1$ on $\{M_\theta \leq |x_1| \leq L\}$. In fact, we have

$$|\nabla\psi| \leq \left(\frac{d}{dt}\eta_L\right)^2 |\psi_{out} - \psi_{in}|^2 + \left((1 - \eta_L)\partial_{x_3}\psi_{in} + \eta_L(-\cos \theta)^2 \right),$$

where we used that $\partial_{x_1}\psi_{in}(x) = 0 \text{ on } \{|x_1| \geq M_\theta\}$. Hence, by convexity of $z \mapsto z^2$, $\eta_L \in [0, 1]$, and $|\partial_{x_3}\psi_{in}| \leq 1$:

$$|\nabla\psi|^2 \leq \left(\frac{d}{dt}\eta_L\right)^2 \sup |\psi_{out} - \psi_{in}|^2 + \left((1 - \eta_L)\partial_{x_3}\psi_{in} + \eta_L(-\cos \theta)^2 \right)^2 \leq 1 \text{ if } L \geq L(\theta) \text{ is sufficiently large.}$$
\[ \Omega = \mathbb{R} \times [-1, 1] \]

Figure 13: \((m_1, m_2)\) on \(\partial \Omega\).

**Step 7:** The degree of \((m_1, m_2)\). Using \(\eta_L(|x_3|) = 0\) and \(\psi_3 = \psi_2^{(63)} = (1 - \cos \theta) - |x_3 + \cos \theta|\) in a neighbourhood of \(\partial \Omega\), we compute

\[ \nabla \psi_3(x) = \partial_{x_3} \psi_3(x) \text{e}_3 = - \text{sgn}(x_3) \text{e}_3 \quad \text{on} \ \partial \Omega, \]

and therefore, due to \(\psi_{\text{out}} = \psi_{\text{in}}\) on \(\partial \Omega\)

\[ \nabla \psi(x) = \eta_L(|x_1|) \nabla \psi_{\text{out}}(x) + (1 - \eta_L(|x_1|)) \nabla \psi_{\text{in}}(x) \\
= - (\eta_L(|x_1|) \cos \theta + (1 - \eta_L(|x_1|)) \text{sgn}(x_3)) \text{e}_3 \quad \text{on} \ \partial \Omega, \]

or in view of the definition of \(m\) in (57):

\[ m(x) = \left( \eta_L(|x_1|) \cos \theta + (1 - \eta_L(|x_1|)) \text{sgn}(x_3), \text{sgn}(x_1) \sqrt{1 - m_2^2(x), 0} \right) \quad \text{on} \ \partial \Omega. \]

Hence, \((m_1, m_2)\), as a map \(S^1 \to S^1\), has degree \(-1\) on \(\partial \Omega\), cf. Figure 13.

In order to prove that the magnetization \(m\) defined at (57) belongs to \(\dot{H}^1(\Omega)\) it is enough to check that \(f = 1 - |\nabla \psi|^2\) has the property that \(\sqrt{T}\) is Lipschitz in \(\mathbb{R}^2\) where \(\psi\) is the stream function constructed above:

**Lemma 7.** Let \(f \in C^2(\mathbb{R}^N, \mathbb{R}_+)\) be a non-negative function with \(D^2 f \in L^\infty(\mathbb{R}^N)\). Then \(\nabla \sqrt{T} \in L^\infty(\mathbb{R}^N)\) and we have

\[ \|\nabla \sqrt{f}\|_\infty \leq \frac{1}{2} \|D^2 f\|_\infty. \]  

**Proof.** We distinguish two cases:

**Case 1:** \(D^2 f \equiv 0\) on \(\mathbb{R}^N\), i.e., \(f\) is an affine function. Since by assumption \(f \geq 0\) in \(\mathbb{R}^N\), one has \(f \equiv \text{const}\). Thus, the assertion of Lemma 7 becomes trivial.

**Case 2:** \(\|D^2 f\|_\infty > 0\). Let \(x, x_0 \in \mathbb{R}^N\). Taylor’s expansion yields for some intermediate \(\tilde{x} \in \mathbb{R}^N:\)

\[ 0 \leq f(x) = f(x_0) + \nabla f(x_0) \cdot (x - x_0) + \frac{1}{2}(x - x_0) \cdot D^2 f(\tilde{x})(x - x_0) \\
\leq |f(x_0)| + \nabla f(x_0) \cdot (x - x_0) + \frac{1}{2} \|D^2 f\|_\infty |x - x_0|^2. \]  

44
Hence, choosing $x \in \mathbb{R}^N$ such that $x - x_0 = -\frac{\nabla f(x_0)}{\|D^2 f\|_\infty}$, we obtain

$$\frac{\|\nabla f(x_0)\|^2}{\|D^2 f\|_\infty} \leq 2|f(x_0)|,$$

i.e.

$$|\nabla \sqrt{f(x_0)}| \leq \frac{1}{\sqrt{2}}\|D^2 f\|_\infty^{\frac{1}{2}} \text{ if } f(x_0) \neq 0. \quad (70)$$

If there exist points at which $f$ vanishes, we apply (70) to $f + \varepsilon$ instead of $f$ (with $\varepsilon > 0$), and deduce for $x, y \in \mathbb{R}^N$

$$|\sqrt{f(x) + \varepsilon} - \sqrt{f(y) + \varepsilon}| \leq \int_0^1 |(\nabla \sqrt{f + \varepsilon}(tx + (1-t)y)| |x - y| dt$$

$$\leq \frac{1}{\sqrt{2}}\|D^2 f\|_\infty |x - y|.$$

Letting $\varepsilon \downarrow 0$ we obtain $|\sqrt{f(x)} - \sqrt{f(y)}| \leq \frac{1}{\sqrt{2}}\|D^2 f\|_\infty^{\frac{1}{2}} |x - y|$ for all $x, y \in \mathbb{R}^N$, such that (68) follows.

\[\square\]

**B Proof of Lemma 2**

The relation between the topological degree of $(m_1, m_2)$ on $\partial \Omega$ and the vortex singularity of $(m_1, m_3)$ observed in the previous construction is studied in Lemma 2 that we prove in the following:

*Proof of Lemma 2.* Due to \( \nabla \cdot m' = 0 \) in \( \mathcal{D}'(\mathbb{R}^2) \) we may represent \( m' = \nabla^\perp \psi \) for a stream function \( \psi: \mathbb{R}^2 \to \mathbb{R} \) with \( \psi(x_1, -1) = 0, \psi(x_1, 1) = -2 \cos \theta \) for all \( x_1 \in \mathbb{R} \). Under the hypothesis \( m \in H^1(\Omega, \mathbb{S}^2) \), one gets that \( \nabla \psi \in H^1(\Omega, \mathbb{S}^2) \). Since \( m \) has non-zero topological degree on \( \mathcal{B}_{dry} \), the set \( \{x \in \partial \Omega \mid m_1(x) < 0\} \) is non-empty (recall that \( m \in H^{1/2}(\partial \Omega, \mathbb{S}^2) \)). We assume that it has non-empty intersection with \( \mathbb{R} \times \{-1\} \). (The other case is similar.) Since \( m_1 = -\partial_{x_3} \psi < 0 \) and \( \psi = 0 \) on that subset of \( \mathbb{R} \times \{-1\} \), one sees that the set \( \{x \in \Omega \mid \psi > 0\} \) is non-empty. In particular, there exists a connected component \( C \) of \( \{x \in \Omega \mid \psi > 0\} \) whose boundary intersects \( \mathbb{R} \times \{-1\} \) on a set containing an interval (see Figure 14).

Since \( \nabla \psi \in \dot{H}^1(\Omega) \), and taking into account the boundary conditions at \( x_1 = \pm \infty \), the Sobolev embedding theorem on sets \( \{a \leq |x_1| \leq a + 1\} \) yields \( \psi(x_1, x_3) \to -(x_3 + 1) \cos \theta \) uniformly in \( x_3 \) as \( |x_1| \to \infty \). Hence, any level set \( \{\psi = \varepsilon\} \) for \( \varepsilon > 0 \) is bounded, and \( \psi \) attains a maximum \( x_0 \) in the interior of \( C \subset \Omega \). Let \( \beta_0 = \psi(x_0) > 0 \).

In the case of a vector field \( m \in C^1(\Omega) \), so \( \psi \in C^2(\Omega \subset \mathbb{R}^2, \mathbb{R}) \), by Sard’s theorem, there exists a regular value \( \beta \in (0, \beta_0) \) of \( \psi \). In particular, there exists a smooth cycle \( \gamma \subset C \) such that \( \psi \equiv \beta \) and \( |\nabla \psi| > 0 \) on \( \gamma \). Therefore, \( \nu := \frac{\nabla \psi}{|\nabla \psi|}: \gamma \to \mathbb{S}^1 \) is a normal vector field at \( \gamma \) so that it carries a topological degree equal to 1. Hence, \( (m_1, m_3) = \nabla^\perp \psi \) presents a
vortex singularity inside $\Omega$ carrying a non-zero winding number. This argument is still valid for the general case $m \in H^1(\Omega)$ (where $\nabla \psi \in H^1(\Omega)$); in fact, Sard’s theorem is valid also for $\psi \in W^{2,1}_{\text{loc}}(C)$ (see e.g., Bourgain-Korobkov-Kristensen [3]) where we recall that $\psi > 0$ on $C$ and $\psi = 0$ on $\partial C$ so that almost all $\beta \in (0, \beta_0)$ is a regular value, i.e., the pre-image $\psi^{-1}(\beta)$ is a finite disjoint family of $C^1$-cycles and the normal vector field $\nu$ on each cycle is absolutely continuous, in particular, it carries a winding number 1.
