A COMMUTATOR DESCRIPTION OF THE SOLVABLE RADICAL OF A FINITE GROUP

NIKOLAI GORDEEV, FRITZ GRUNEWALD, BORIS KUNYAVSKII, EUGENE PLOTKIN

Abstract. We are looking for the smallest integer $k > 1$ providing the following characterization of the solvable radical $R(G)$ of any finite group $G$: $R(G)$ coincides with the collection of $g \in G$ such that for any $k$ elements $a_1, a_2, \ldots, a_k \in G$ the subgroup generated by the elements $g, a_ig a_i^{-1}, i = 1, \ldots, k$, is solvable. We consider a similar problem of finding the smallest integer $\ell > 1$ with the property that $R(G)$ coincides with the collection of $g \in G$ such that for any $\ell$ elements $b_1, b_2, \ldots, b_\ell \in G$ the subgroup generated by the commutators $[g, b_i], i = 1, \ldots, \ell$, is solvable. Conjecturally, $k = \ell = 3$. We prove that both $k$ and $\ell$ are at most 7. In particular, this means that a finite group $G$ is solvable if and only if in each conjugacy class of $G$ every 8 elements generate a solvable subgroup.

1. INTRODUCTION

1.1. Main results. Let $F_2 = F(x, y)$ be the free two generator group. Define a sequence $\vec{e} = e_1, e_2, e_3, \ldots$, where $e_i(x, y) \in F_2$, by
\[
e_1(x, y) = [x, y] = xyx^{-1}y^{-1}, \ldots, e_n(x, y) = [e_{n-1}(x, y), y], \ldots
\]

An element $g$ of a group $G$ is called an Engel element if for every $a \in G$ there exists a number $n = n(a, g)$ such that $e_n(a, g) = 1$.

In 1957 R. Baer proved the following theorem [Ba], [H]:

**Theorem 1.1.** The nilpotent radical of a noetherian group $G$ coincides with the collection of all Engel elements of $G$.

In particular, Baer’s theorem is true for finite groups. Similar theorems have been established for many classes of infinite groups satisfying some additional conditions (see for example [Plo], [Pla]).

A tempting but difficult problem is to find a counterpart of Baer’s theorem for the solvable radical of a finite group, in other words, to find an Engel-like sequence $\vec{u} = u_1(x, y)$ such that an element $g$ of a finite group $G$ belongs to the solvable radical $R(G)$ of $G$ if and only if for any $a \in G$ there exists a number $n = n(a, g)$ such that $u_n(a, g) = 1$.

The first results towards a solution of this problem have been obtained in [BGGKP1], [BGGKP2], [BWW], and [BBGKP].

In the paper [GKPS] a Thompson-like characterization of the solvable radical of finite groups (and, more generally, linear groups and PI-groups) has been obtained.

**Theorem 1.2.** [GKPS] The solvable radical $R(G)$ of a finite group $G$ coincides with the set of all elements $g \in G$ with the following property: for any $a \in G$ the subgroup generated by $g$ and $a$ is solvable.

This theorem can be viewed as an implicit description of the solvable radical since it does not provide any explicit formulas which determine if a particular element belongs to $R(G)$.
In the present paper our goal is to obtain a new characterization of the solvable radical $R(G)$ of a finite group $G$.

**Theorem 1.3.** The solvable radical of any finite group $G$ coincides with the collection of $g \in G$ satisfying the property: for any 7 elements $a_1, a_2, \ldots, a_7 \in G$ the subgroup generated by the elements $g, a_ia_i^{-1}$, $i = 1, \ldots, 7$, is solvable.

The proof involves the classification of finite simple groups.

This theorem implies the following characterization of finite solvable groups:

**Theorem 1.4.** A finite group $G$ is solvable if and only if in each conjugacy class of $G$ every 8 elements generate a solvable subgroup.

We hope to sharpen these results.

**Conjecture 1.5.** The solvable radical of a finite group $G$ coincides with the collection of $g \in G$ satisfying the property: for any 3 elements $a, b, c \in G$ the subgroup generated by the conjugates $g, aga^{-1}, bgb^{-1}, cg^{-1}$ is solvable.

This statement implies

**Conjecture 1.6.** A finite group $G$ is solvable if and only if in each conjugacy class of $G$ every four elements generate a solvable subgroup.

**Remark 1.7.** These characterizations are the best possible: in the symmetric groups $S_n$ ($n \geq 5$) any triple of transpositions generates a solvable subgroup.

**Remark 1.8.** The main step in our proof of Theorem 1.3 is Theorem 1.11 below. To prove Conjecture 1.5 (and hence Conjecture 1.6), one has to extend the statement of Theorem 1.11 to all almost simple groups, i.e. to the groups $H$ such that $G \leq H \leq \text{Aut}(G)$ for some simple group $G$.

**Remark 1.9.** The statements of Theorems 1.3 and 1.4 remain true for arbitrary linear groups. Once Conjectures 1.5 and 1.6 are proved, they can also be extended to arbitrary linear groups.

Throughout the paper $\langle a_1, \ldots, a_k \rangle$ stands for the subgroup of $G$ generated by $a_1, \ldots, a_k \in G$. We define the commutator of $x, y \in G$ by $[x, y] = xyx^{-1}y^{-1}$. 

Definition 1.10. Let $k \geq 2$ be an integer. We say that $g \in G$ is a $k$-radical element if for any $a_1, \ldots, a_k \in G$ the subgroup $H = \langle [a_1, g], \ldots, [a_k, g] \rangle$ is solvable.

We prove the following result.

Theorem 1.11. Let $G$ be a finite nonabelian simple group. Then $G$ does not contain nontrivial 3-radical elements.

This theorem implies Theorems 1.3 and 1.4.

The proof goes by case-by-case inspection of simple groups (alternating groups, groups of Lie type, sporadic groups). In fact we prove a more precise result (Theorem 1.15) which distinguishes between 2-radical and 3-radical elements.

The following simple fact allows us to define a new invariant of a finite group.

Proposition 1.12. Let $G$ be a group which has no nontrivial solvable normal subgroups. Then for every $g \in G, g \neq 1$ the group $H_g = \langle [g, G] \rangle$ is not solvable.

Proof. For every $x, y \in G$ we have

$$[g, x]^{-1}[g, y] = (xgx^{-1}g^{-1})(gyg^{-1}y^{-1}) = (xgx^{-1})(gyg^{-1}y^{-1}) \in H_g.$$ 

Thus, $C_g C_{g^{-1}} \subseteq H_g$ where $C_g, C_{g^{-1}}$ are the corresponding conjugacy classes. Since the set $C_g C_{g^{-1}}$ is invariant under conjugation, the subgroup $F = \langle C_g C_{g^{-1}} \rangle \leq H_g$ is normal in $G$ and therefore cannot be solvable. \hfill \Box

Corollary 1.13. Let $G$ be a finite group, and let $R(G)$ denote the solvable radical of $G$. Then $g \notin R(G)$ if and only if there exist an integer $n$ and $x_1, \ldots, x_n \in G$ such that the subgroup $\langle [g, x_1], \ldots, [g, x_n] \rangle$ is not solvable.

Definition 1.14. Denote by $\rho(g)$ the smallest possible $n$ with the following property: $g \notin R(G)$ if and only if there exist $x_1, \ldots, x_n \in G$ such that the subgroup $\langle [g, x_1], \ldots, [g, x_n] \rangle$ is not solvable. We call the number $\rho(G) := \max_{g \in G \setminus R(G)} \rho(g)$ the radical degree of $G$.

In these terms we have to prove that the radical degree of a finite nonabelian simple group $G$ is $\leq 3$. Our most precise result, which implies Theorem 1.11 and, correspondingly, Theorems 1.3 and 1.4, is the following
Theorem 1.15. If $G$ is a finite nonabelian simple group, then $\rho(G) \leq 3$. If $G$ is a group of Lie type over a field $K$ with $\text{char} K \neq 2$ and $K \neq \mathbb{F}_3$, or a sporadic group not isomorphic to $Fi_{22}$ or $Fi_{23}$, then $\rho(G) = 2$.

1.2. Notation and conventions. First introduce some standard notation which mostly follows [St], [Ca1], [Ca2].

Denote by $G = G(\Phi, K)$ a Chevalley group where $\Phi$ is a reduced irreducible root system and $K$ is a field. Assume that $\Phi$ is generated by a set of simple roots $\Pi = \{\alpha_1, \ldots, \alpha_r\}$, that is $\Phi = \langle \alpha_1, \ldots, \alpha_r \rangle$. We number the roots according to [Bou]. Let $W = W(\Phi)$ be the Weyl group corresponding to $\Phi$. Denote by $\Phi^+$, $\Phi^-$ the sets of positive and negative roots, respectively.

We use the standard notation $u_\alpha(t)$, $\alpha \in \Phi$, $t \in K$, for elementary root unipotent elements of $G$. Correspondingly, split semisimple elements will be denoted by $h_\alpha(t)$, $t \in K^*$, where $K^*$ is the multiplicative group of $K$. For $\alpha \in \Phi$, let $U_\alpha$ denote the root subgroup generated by all elementary root unipotent elements $u_\alpha(t)$.

For the sake of completeness, recall that $w_\alpha(t) = u_\alpha(t)x_{-\alpha}(-t^{-1})u_\alpha(t)$, $w_\alpha = w_\alpha(1)$ and $h_\alpha(t) = w_\alpha(t)w_\alpha^{-1}$. Define the subgroups $U = U^+ = \langle u_\alpha(t), \alpha \in \Phi^+, t \in K \rangle$, $V = U^- = \langle u_\alpha(t), \alpha \in \Phi^-, t \in K \rangle$, $T = \langle h_\alpha(t), \alpha \in \Phi, t \in K^* \rangle$, and $N = \langle w_\alpha(t), \alpha \in \Phi, t \in K^* \rangle$.

As usual, the Borel subgroups $B^\pm$ are $B = B^+ = TU$, $B^- = TU^-$. The group $N$ contains $T$, and $N/T \cong W$. Denote by $\breve{w}$ a preimage of $w \in W$ in $N$.

We also consider twisted Chevalley groups over finite fields. Assume that $K$ is a finite field of characteristic $p$ and $|K| = q = p^s$. By a twisted Chevalley group we mean the group $G^F = G^F(\Phi, \overline{K})$ of fixed points of the simply connected Chevalley group $G(\Phi, \overline{K})$ under the Frobenius map $F$ (see [St], [Ca1], [Ca2]). Here $\overline{K}$ stands for the algebraic closure of $K$. Let $\theta$ be the field automorphism corresponding to $F$. Denote by $k = K^\theta$ the subfield of $\theta$-fixed points for all cases except for the Suzuki groups and the Ree groups. For the latter groups suppose that $k = K$. Let $\gamma$ be the graph automorphism corresponding to $F$. We denote by $\Phi^\gamma$ the root system which determines the structure of the group $G^F = G^F(\Phi, \overline{K})$. Elementary root unipotent elements $u_\alpha(t)$, $\alpha \in \Phi^\gamma$, have either one parameter $t \in K$ or $t \in k$. 

or two parameters \(u_t, u \in K\) (for the cases \(A_2, B_2, F_4\)), or three parameters \(u_t, u, v \in K\) (for \(G_2\), see [St]. Again, the root subgroups \(U_\alpha\) are generated by root unipotent elements. The subgroups \(B^F, W^F, T^F, H^F, U^\pm F\) in \(G^F\) are defined in a standard way, see [Ca2]. A maximal torus of \(G^F\) is a subgroup of the form \(T^F\), where \(T\) is an \(F\)-stable maximal torus of \(G\). A maximal torus \(T^F\) is called quasisplit if it is contained in \(B^F\). Throughout the paper we suppress the map \(F\) in the notations. We also suppress \(\gamma\) in the notation of the root system corresponding to the group \(G^F\). Whenever we need to specify the type of a group, it will be written explicitly.

We follow [Ca2] in the notation of twisted forms. Thus unitary groups are denoted by \(PSU_n(q^2)\) (and not by \(PSU_n(q)\)), the notation \(2F_4(2m+1)\) means that \(q = \sqrt{2^{2m+1}}\), etc.

The paper is organized as follows. In Section 2 we reduce Theorem 1.4 to Theorem 1.15. In Sections 3–9 we prove Theorem 1.15 using case-by-case analysis.

Acknowledgements. Gordeev was partially supported by the INTAS grant N-05-1000008-8118. Kunyavskii and Plotkin were partially supported by the Ministry of Absorption (Israel), the Israeli Science Foundation founded by the Israeli Academy of Sciences — Center of Excellence Program, the Minerva Foundation through the Emmy Noether Research Institute of Mathematics, and by the RTN network HPRN-CT-2002-00287. A substantial part of this work was done during Gordeev’s visits to Bar-Ilan University in May 2005 and May 2006 (partially supported by the same RTN network) and the visit of Grunewald, Kunyavskii and Plotkin to MPIM (Bonn) during the activity on “Geometry and Group Theory” in July 2006. The support of these institutions is highly appreciated.

We are very grateful to J. N. Bray, B. I. Plotkin, and N. A. Vavilov for useful discussions and correspondence.

2. Reduction Theorem

Let us show how Theorem 1.15 implies Theorem 1.4.

Suppose Theorem 1.15 is proven, and let us show that the solvable radical \(R(G)\) of a finite group \(G\) coincides with the collection of \(g \in G\) satisfying the property: for any 7 elements \(a_1, a_2, \ldots, a_7 \in G\) the subgroup generated by the elements \(g, a_iga_i^{-1}, i = 1, \ldots, 7\), is solvable.
For the sake of convenience, let us call the elements \( g \in G \) satisfying the condition of the theorem, suitable.

Suppose \( g \in R(G) \). Since \( R(G) \) is a normal subgroup, \( aga^{-1} \) belongs to \( R(G) \) for any \( a \in G \). Hence for any \( k \) the subgroup \( \langle a_1ga_1^{-1}, \ldots, a_kga_k^{-1} \rangle \), where \( a_1, \ldots, a_k \in G \), is solvable. Therefore, all the elements of \( R(G) \) are suitable.

Suppose now that \( g \in G \) is a suitable element. We want to show that \( g \) belongs to \( R(G) \). It is enough to prove that there are no non-trivial suitable elements in the semisimple group \( G/R(G) \). So one can assume that the group \( G \) is semisimple in the sense that \( R(G) = 1 \).

As usual we consider a minimal counterexample \( G \) to the statement above.

Recall that any finite semisimple group \( G \) contains a unique maximal normal centreless completely reducible (CR) subgroup (by definition, CR means a direct product of finite non-abelian simple groups) called the CR-radical of \( G \) (see [Ro, 3.3.16]). We call a product of the isomorphic factors in the decomposition of the CR-radical \( V \) of \( G \) an isotypic component of \( G \). Denote the CR-radical of \( G \) by \( V \). This is a characteristic subgroup of \( G \).

Let us show that \( V \) has only one isotypic component. Suppose \( V = N_1 \times N_2 \), where \( N_1 \cap N_2 = 1 \). Consider \( \bar{G} = G/N_1 \) and denote \( \bar{R} = R(G/N_1) \). Consider a suitable \( g \in G \), \( g \neq 1 \) and denote by \( \bar{g} \) (resp. \( \bar{g} \)) the image of \( g \) in \( \bar{G} \) (resp. \( \bar{G}/\bar{R} \)). Since \( \bar{G}/\bar{R} \) is semisimple and \( \bar{g} \in \bar{G}/\bar{R} \) is suitable, we have \( \bar{g} = 1 \) (because \( G \) is a minimal counter-example) and hence \( \bar{g} \in R(G/N_1) \). Consider \( V/N_1 \cong N_2 \). Then \( V/N_1 \subset G/N_1 \) is semisimple and therefore \( V/N_1 \cap R(G/N_1) = 1 \). Since \( \bar{g} \in R(G/N_1) \), we have \([\bar{g}, \bar{v}] = 1\) for every \( \bar{v} \in V/N_1 \). Hence \([g, v] \in N_1\) for every \( v \in V \). Similarly, \([g, v] \in N_2\) for every \( v \in V \). Therefore \([g, v] = 1\). Hence \( g \) centralizes every \( v \in V \). Since the centralizer of \( V \) in \( G \) is trivial, we get \( g = 1 \). Contradiction.

Any \( g \in G \) acts as an automorphism \( \tilde{g} \) on \( V = H_1 \times \cdots \times H_n \), where all \( H_i \), \( 1 \leq i \leq n \), are isomorphic nonabelian simple groups.

Suppose that \( g \) is a suitable element. Let us show that \( \tilde{g} \) cannot act on \( V \) as a non-identity element of the symmetric group \( S_n \). Denote by \( \sigma \) the element of \( S_n \) corresponding to \( \tilde{g} \).
By definition, the subgroup $\Gamma = \langle g, x_ix_i^{-1} \rangle$, $i = 1, \ldots, 7$, is solvable for any elements $x_i \in G$. Evidently, the subgroup $\langle [g, x_1], [g, x_2] \rangle$ lies in $\Gamma$.

Suppose $\sigma \neq 1$, and so $\sigma(k) \neq k$ for some $k \leq n$. Take $\bar{x}_1$ and $\bar{x}_2$ of the form $\bar{x}_i = (1, \ldots, x_i^{(k)}, \ldots, 1)$, where $x_i^{(k)} \neq 1$ lies in $H_k$ ($i = 1, 2$). Then we may assume $(\bar{x}_i)^\sigma = (x_i^{(k)}, 1, \ldots, 1)$, and so $[g, \bar{x}_i] = (\bar{x}_i)^\sigma \bar{x}_i^{-1} = (x_i^{(k)}, 1, \ldots, (x_i^{(k)})^{-1}, \ldots, 1)$.

By a theorem of Steinberg, $H_k$ is generated by two elements, say $a$ and $b$. On setting $x_1^{(k)} = a$, $x_2^{(k)} = b$, we conclude that the group generated by $[g, \bar{x}_1]$ and $[g, \bar{x}_2]$ cannot be solvable because the first components of these elements, $a$ and $b$, generate the simple group $H_k$. Contradiction with solvability of $\Gamma$.

So we can assume that a suitable element $g \in G$ acts as an automorphism of a simple group $H$. Then we consider the extension of the group $H$ with the automorphism $\bar{g}$. Denote this almost simple group by $G_1$. We shall use the formula

$$y[x, g]y^{-1} = [x, g][[g, x], y].$$

Since $G_1$ has no centre, one can choose $x \in H$ such that $[x, \bar{g}] \neq 1$. Evidently, $[x, \bar{g}]$ belongs to the simple group $H$. Then by Theorem 1.15, there exist $y_1, y_2, y_3 \in H$ such that the subgroup $\langle [[x, g], y_1], [[x, g], y_2], [[x, g], y_3] \rangle$ is not solvable. But

$$\langle [[x, g], y_1], [[x, g], y_2], [[x, g], y_3] \rangle \leq \langle y_i[x, g]y_i^{-1}, [x, g] \mid i = 1, 2, 3 \rangle \leq \langle g, x^{-1}gx, y_i^{-1}gy_i, y_i^{-1}x^{-1}gxy_i \mid i = 1, 2, 3 \rangle$$

Since $g$ is suitable, the latter subgroup must be solvable. Contradiction with the choice of $y_i$.

### 3. Alternating groups

**Proposition 3.1.** Let $G = A_n$, $n \geq 5$. Then $\rho(G) = 2$.

**Proof.** For $n = 5, 6$ the statement can be checked in a straightforward manner, so assume $n \geq 7$. Let us proceed by induction. Let $y \in G$, $y \neq 1$. First suppose that $y$ can be written in the form

$$y = \sigma \tau, \sigma \in A_m, \sigma \neq 1, m < n.$$
Then by induction hypothesis there exist $\sigma_1, \sigma_2 \in A_m$ such that the subgroup generated by $[\sigma, \sigma_1]$ and $[\sigma, \sigma_2]$ is not solvable. Take $x_i = \sigma_i \tau$, $i = 1, 2$. Then $[y, x_i] = [\sigma, \sigma_i]$, and we are done.

Suppose $y$ cannot be represented in the form (3.1). Then we have one of the following cases: either $n$ is odd and $y = (12\ldots n)$, or $n$ is even and $y = (12\ldots n - 2)(n - 1, n)$. In any of these cases we take $x_1 = (123)$ and $x_2 = (345)$ and get $([x_1, y], [x_2, y]) \cong A_5$. \hfill \Box

4. Groups of Lie type of rank 1 over fields of large characteristic

**Proposition 4.1.** Let $G$ be one of the groups $A_1(q)$ ($q \neq 2, 3$), $^2A_2(q^2)$ ($q \neq 2$), $^2B_2(2^{2m+1})$ ($m \geq 1$), $^2G_2(3^{2m+1})$ ($m \geq 0$). Then $\rho(G) = 2$.

**Remark 4.2.** Obviously, it is enough to prove that $\rho(G_1) = 2$ for some group $G_1$ lying between $G$ and its simply connected cover. In each specific case the choice of $G_1$ will depend on the convenience of the proof. In particular, we shall often assume the Chevalley group under consideration to be simply connected. We shall use this observation without any special notice.

We start with computations for simple groups of Lie type of small Lie rank defined over $\mathbb{F}_2$ and $\mathbb{F}_3$. They will be used in several parts of our proof. The computations were made for all groups of rank 1 and 2 and also for certain groups of rank 3 and 4 needed for our arguments. The results of MAGMA computations are exhibited in Table 1. Each entry displays the number of 2-radical elements in the corresponding group (up to conjugacy) and their orders (in parentheses). Dash means that the corresponding group either is solvable or does not exist (for this reason the types $A_1$ and $^2B_2$ do not appear at all). Asterisks mean that the corresponding group $G$ is not simple, and computations were made for the derived subgroup $G'$, which is simple. It is worth recalling the isomorphisms $B_2(q) \cong C_2(q)$, $B_2(3) \cong C_2(3) \cong ^2A_3(2^2)$, $G_2(2)' \cong ^2A_2(3^2)$, $A_3(2) \cong A_8$.

Before starting the proof of the proposition, we recall the following result from [Gow] (compare with [EG2]) regarding conjugacy classes of semisimple elements in Chevalley groups. This fact is essential for our arguments.

**Theorem 4.3.** [Gow] Let $G$ be a finite simple group of Lie type, and let $g \neq 1$ be a semisimple element in $G$. Let $L$ be a conjugacy class
of $G$ consisting of regular semisimple elements. Then there exist a regular semisimple $x \in L$ and $z \in G$ such that $g = [x, z]$.

Let us now go over to the proof of Proposition 4.1.

**Proof.** First note that for the groups $G = 2A_2(3^2)$ and $G = 2G_2(3^2)$ the statement of the proposition follows from calculations presented in Table 1. So we exclude these groups from consideration in the rest of the proof. We start with several simple lemmas (recall that $G$ is a finite group).

**Lemma 4.4.** Let $G = B \cup BwB$ be a group of rank one. Let $1 \neq u \in U$. If $gug^{-1} \in U$, then $g \in B$.

**Proof.** Suppose $g = u_2wu_1$ where $u_1, u_2 \in U$. Then $v = u_2w_1uu_1w_1u_2^{-1} \in U$. Hence

$$U \ni u_2^{-1}vu_2 = w_1uu_1^{-1}w_1^{-1} \in U^-.$$

This contradicts the assumption $u \neq 1$. \hfill \Box

**Lemma 4.5.** Let $G$ be a group of rank one. Then every nontrivial unipotent element is contained in only one Borel subgroup.

**Proof.** Suppose $1 \neq u \in U \leq B$ and $u \in B'$, where $B' = xBx^{-1}$, $x \notin B$ [St]. Then $u = xv_1^{-1}$ for some $v \in U$. By Lemma 4.4, $x \in B$, contradiction. \hfill \Box
Lemma 4.6. Let $G$ be a group of rank one. Then, up to conjugacy, for every $g \in G$ we have either $g \in T$, or $g \in U$, or $g = tu$ with $t \in T, u \in U, tu = ut$, or $g$ is a regular semisimple element which is not contained in any Borel subgroup.

Proof. Indeed, let $g = su = us$ be the Jordan decomposition of $g$. We may and shall assume $u \in U$. If $s = 1$, then $g = u \in U$, so we assume further $s \neq 1$. Suppose $us^{-1} = u \in U$ and therefore, by Lemma 4.4, we have $s \in B$. Since $s \in B$, $s$ lies in some quasisplit torus. As all quasisplit tori are conjugate [Ca2], we have $s = bsb^{-1} \in T$ for some $b \in B$. Thus we get

$$bg^{-1} = bsb^{-1}bub^{-1} = s'u'$$

with $s' \in T, u' \in U$. Suppose now $u = 1$. We have $g = s$, and if $s$ lies in a Borel subgroup, then $s$ is conjugate to an element of $T$, as above. Finally, if $s$ is a semisimple element which does not belong to any Borel subgroup, then according to Lemma 4.4 it does not commute with any unipotent element, and thus $g = s$ is a regular semisimple element. \qed

Definition 4.7. Let $t \in T$. Define

$$[t^2] := wt^{-1}w.$$  

If $G$ is of the type $A_1, B_2$, or $G_2$, we have $t^2 = t$. If $G$ is of the type $2A_2(q^2)$ and $t = \text{diag}(\lambda, \lambda^{-1}\lambda^q, \lambda^{-q})$, we have $t^2 = \text{diag}(\lambda\lambda^q, 1, \lambda^{-1}\lambda^{-q})$.

Lemma 4.8. Let $G$ be a group of rank one, let $g \notin Z(G)$, and let $t$ be a generator of $T$. Suppose $t^2$ is a regular element. Then there exists $x \in G$ such that $[g, x]$ is of the form $t^2$ where $\rho$ is a generator of a quasisplit torus of $G$.

Proof. We may assume $g = uw$. Put $x = t^{-1}$. Then

$$\sigma = [g, t^{-1}] = uwt^{-1}w^{-1}tt^{-1}u^{-1}t = ut^2t^{-1}u^{-1}t$$

which is conjugate to $t^2v$ for some $v \in U$. Since $t^2v$ and, correspondingly, $t^{-2}$ are regular elements, there exists $y$ such that $v = [t^{-2}, y]$ (see, for example, [EG2]). Then $yt^2y^{-1} = t^2[t^{-2}, y] = t^2v$. Put $\rho = yty^{-1}$. Then $\rho$ is a generator of a quasisplit torus $T' = Tyy^{-1}$ and $w_1 = ywy^{-1}$ is a preimage of the generator of the Weyl group. We have
yt^{[2]}y^{-1} = y \tilde{w}^{-1} \tilde{w}^{-1} t y^{-1} = (y \tilde{w} y^{-1})(yt^{-1}y^{-1})(y \tilde{w}^{-1} y^{-1})(yt y^{-1}) \\
= \tilde{w}_{1} \rho^{-1} w_{1}^{-1} \rho = \rho^{[2]}.

\[ \square \]

**Remark 4.9.** Explicit calculations with the matrices

\[
t = \text{diag}(\lambda, \lambda^{-1}), \\
t = \text{diag}(\lambda, \lambda^{-1} \lambda^{q}, \lambda^{-q}), \\
t = \text{diag}(\lambda, \lambda^{2/q-1}, \lambda^{-1}, \lambda^{1-2q}), \\
t = \text{diag}(\lambda^{9}, \lambda^{1-\theta}, \lambda^{2q-1}, 1, \lambda^{1-2q}, \lambda^{\theta-1}, \lambda^{-\theta}),
\]

corresponding, respectively, to the natural representation of $SL_{2}(q)$, natural representation of $SU_{3}(q^{2})$, 4-dimensional representation of the Suzuki group and 7-dimensional representation of the Ree group, show that the hypothesis of Lemma 4.8 holds for every group from Proposition 4.1 except for $A_{1}(5)$ which we can throw away because $PSL_{2}(5) \cong A_{5}$.

**Lemma 4.10.** Let $T'$ be a quasisplit torus in a group $G$ of rank 1, and let $S$ be a subgroup of $T'$ such that $C_{G}(S) = T'$. Then $N_{G}(S) = N_{G}(T')$.

**Proof.** Let $B' = T'U'$ be a Borel subgroup containing $T'$, and let $G = B' \cup B' \tilde{w}' B'$ be the corresponding Bruhat decomposition. Let $g \in N_{G}(S)$. Suppose $g = u_{1} \tilde{w}'u_{2}$ where $u_{1}, u_{2} \in U'$. Then for every $s \in S$ we have

$$g s g^{-1} = (u_{1} \tilde{w}'u_{2}) s (u_{2}^{-1} \tilde{w}'^{-1} u_{1}^{-1}) = s' \in S \Rightarrow$$

$$\Rightarrow B^{'-} \supseteq (\tilde{w}' s \tilde{w}'^{-1})(\tilde{w}' [s^{-1}, u_{2}] \tilde{w}'^{-1}) = s' [s^{-1}, u_{1}^{-1}] \in B^{'-}\cap B' \Rightarrow s^{-1}, u_{2} = 1 \Rightarrow s \in N_{G}(T').$$

Suppose $g \in B'$. Then $g = tu$ for some $t \in T'$, $u \in U'$, and for every $s \in S$ we have

$$g s g^{-1} = st [s^{-1}, u] t^{-1} \in S \Rightarrow [s^{-1}, u] = 1 \Rightarrow u = 1.$$ 

Hence $g \in N_{G}(T')$ and therefore $N_{G}(S) \leq N_{G}(T')$.

Further, using the same arguments as above (put $S = T'$) one can see that $N_{G}(T') = \langle T', \tilde{w}' \rangle$. Note that the conjugation with $w'$ is an automorphism of $T'$ and $T'$ is a cyclic group. Hence the conjugation with $w'$ is an automorphism of $S$. Thus $N_{G}(T') \leq N_{G}(S).$ \[ \square \]
Lemma 4.11. Suppose the hypothesis of the previous lemma holds. Suppose that for every non-regular $s \in T$ and for every regular $t \in T$ the element $st$ is regular. Then for every $g \not\in Z(G)$ there exist $x, y \in G$ such that the group $H$ generated by $\tau = [g, x]$ and $\sigma = [g, y]$ is not contained in any Borel subgroup. Moreover, $\tau \notin N(\langle \sigma \rangle)$.

Proof. We shall divide the proof into two cases: 1) $g$ is not a regular semisimple element; 2) $g$ is a regular semisimple element. Case 1, in turn, will be subdivided into two subcases: 1a) $\text{char}(K) \neq 2$; 1b) $\text{char}(K) = 2$.

Case 1a) First suppose $g$ is not a regular semisimple element. By Lemma 4.6, we have $g \in B$, $g = su$ with $su = us$, $s \in T$ is a non-regular element, and $u \in U$. Then we can get $1 \neq \tau = [g, x] \in U$. Indeed, if $u \neq 1$, we take $x = s_1 \in T$ such that $[u, s_1] \neq 1$. Then $[g, x] = [g, s_1] = [us, s_1] = [s, s_1]^u[u, s_1] = [u, s_1] = us_1u^{-1}s_1^{-1} \in U$. If $u = 1$, then $s \notin Z(G)$, and hence $1 \neq [s, v] \in U$ for some $v \in U$.

Then by Lemma 4.8, we get $\sigma = [g, y] = \rho^{[2]}$ where $\rho$ is a generator of a quasisplit torus. Suppose $\langle \tau, \sigma \rangle = H \leq B'$ for some Borel subgroup $B'$. Since $\tau$ is a unipotent element, by Lemma 4.5 we have $B' = B$ and therefore $g yg^{-1} y^{-1} = \sigma \in B$. Consider the element $g^{-1}\sigma = u^{-1}s^{-1}\sigma$. Since $\sigma \in B$, we have $\sigma = s'u'$ where $s' \in T$ is semisimple and $u' \in U$. Since $\sigma$ is regular, so is $s'$. Then $g^{-1}\sigma = u^{-1}s^{-1}s'u' = s^{-1}u^{-1}s'u' = s^{-1}s'u_1u' = s^{-1}u''$ for some $u'' \in U$. By the hypothesis of the lemma, $s^{-1}s'$ is a regular semisimple element. Hence $g^{-1}\sigma = s^{-1}s'u''$ is a regular semisimple element. Contradiction, since $yg^{-1}y^{-1} = g^{-1}\sigma$ is not a regular semisimple element.

Let us now prove that $\tau \notin N_G(\langle \sigma \rangle)$. Assume the contrary. Since $\sigma$ is a regular semisimple element, we have $C_G(\sigma) = C_G(\langle \sigma \rangle) = T'$. Lemma 4.10 gives $N_G(\langle \sigma \rangle) = N_G(T')$. Therefore $\tau \in N_G(T')$.

Hence $\tau^2 \in T'$. Indeed, since $\tau \in N_G(T')$, we have $\tau = \hat{w}'$ where $\hat{w}'$ is a preimage of an element of the Weyl group (possibly, $\hat{w}' = 1$) corresponding to $T'$. Thus $\tau^2 \in T'$. But $\tau \in U$. Hence $\tau$ is a unipotent element of order 2 which contradicts to the assumption $\text{char}(k) \neq 2$.

Case 1b) Suppose $g$ is not a regular semisimple element and $\text{char}(k) = 2$. In this case we may assume $g = \hat{w}$.

Indeed, let $g = su$ be the Jordan form for $g$. Suppose the order of $u$ is greater than 2. On setting $x = t \in T$, we get the element $[g, x] \in U$ of order greater than 2. Then, by the arguments of Case 1a, we have
\[ \tau \notin N_G(\langle \sigma \rangle). \] Thus the order of \( u \) is one or two. As \( \text{char}(k) = 2 \), every non-regular element of \( T \) lies in the centre of \( G \), and therefore we may assume \( s = 1 \). Hence we may assume \( g = u \) to be an element of order 2.

As \( \text{char}(k) = 2 \), in each of the Lie rank one groups, \( SL_2(2^m) \), \( SU_3(2^{2m}) \), \( 2B_2(2^{2m+1}) \), all involutions are conjugate, and we may assume \( g = \hat{w} \).

Therefore we can take \( \sigma = [g, t] = [\hat{w}, t] = t^{[2]} \), and \( \tau = [g, u] = [\hat{w}, u] = \hat{w}u\hat{w}^{-1} = vu^{-1} \) where \( u \in U \) and \( 1 \neq v \in U^- \). Suppose \( \sigma, \tau \in B' \) for some Borel subgroup \( B' \). Then \( T \leq B' \) and therefore \( B' = B \) or \( B' = B^- \). Contradiction, since \( \tau \notin B, \tau \notin B^- \).

Suppose now \( \tau = vu^{-1} \in N_G(\langle \sigma \rangle) = N_G(T) \). This is impossible: \( vu^{-1}tuv^{-1} = t' \in T \Rightarrow (B \setminus T) \ni u^{-1}tu = v^{-1}t'v \in (B^- \setminus T) \).

**Case 2.** Let \( g \) be a regular semisimple element. By [Gow], we can get \( \sigma = [g, y] \) to be a generator of a quasisplit torus and \( \tau = [g, x] \) to be a regular semisimple element which is not contained in any Borel subgroup.

We have

| \( T \) | = \( q - 1 \) if \( G = SL_2(q) \);
| \( T \) | = \( q^2 - 1 \) if \( G = SU_3(q^2) \) or \( G \) is a Suzuki or a Ree group.

Further,

\((q + 1)\) divides \( |G| \) if \( G = SL_2(q) \), \((q + 1, q - 1) = 2 \) or 1 (if \( q \) is even);

\((q^2 - q + 1)\) divides \( |G| \) if \( G = SU_3(q^2) \), \((q^2 - 1, q^2 - q + 1)\) equals 3 or 1 (indeed, \( p \) divides \((q - 1)\) implies \( q \equiv 1 \) (mod \( p \)), hence \( q^2 - q + 1 \equiv 1 \) (mod \( p \))). Correspondingly, \( p \mid q + 1 \) implies \((q^2 - q + 1) \equiv 3 \) (mod \( p \));

\((q^4 + 1)\) divides \( |G| \) if \( G \) is a Suzuki group, \( q^2 = 2^{2m+1} \), \((q^2 - 1, q^4 + 1) = 1 \);

\((q^4 - q^2 + 1)\) divides \( |G| \) if \( G \) is a Ree group, \( q^2 = 3^{2m+1} \), \((q^4 - q^2 + 1, q^2 - 1) = 1 \).

Let now \( G = SL_2(q) \). Then the maximal nonsplit torus is a cyclic group of order \( q + 1 \). By [Gow], we can take \( \tau = [g, y] \) to be a generator of such a group. Then the order of \( \tau^2 \) is equal to \( q + 1 > 2 \) if \( q = 2^m \) or \((q + 1)/2 > 2 \) (note that \( q > 3 \)). Hence \( \tau \notin N_G(\langle \sigma \rangle) = N_G(T) \) (because \( \tau^2 \notin T \)). Also \( \tau \) does not belong to a Borel subgroup.
Let $G = SU_3(q^2)$. Suppose that 3 divides $q^2 - q + 1$. Then $q \equiv -1 \pmod{3}$, hence $q \equiv 2, 5, 8 \pmod{9}$ and, therefore, 9 does not divide $q^2 - q + 1$. Then there exists a prime $p \neq 2, 3, p \mid q^2 - q + 1$. By [Gow], we can obtain an element of order $p$ of the form $\tau = [g, y]$. Then $\tau \notin N_G(\langle \sigma \rangle)$, and $\tau$ does not belong to a Borel subgroup.

If $G$ is of Suzuki or Ree type, take $p = q^4 + 1$ or $p = q^2 + 1$, respectively, and proceed as above.

Thus, in all the cases $\tau \notin N_G(\langle \sigma \rangle)$. \qed

**Remark 4.12.** The hypotheses of Lemma 4.11 hold for every group from Proposition 4.1. This can also be checked by explicit calculations with diagonal matrices (see [Ca2] and [KLM]).

**Lemma 4.13.** There exist $\tau = [g, x]$ and $\sigma = [g, y]$ such that the subgroup $H = \langle \sigma, \tau \rangle$ is not solvable.

We choose $\tau = [g, x]$ and $\sigma = [g, y]$ as in the previous lemma.

It is enough to show that $H$ does not contain abelian normal subgroups. Let $A$ be a maximal abelian normal subgroup of $H$. We want to check that $A$ is a reductive group. Suppose $p = \text{char}(K)$ divides the order of $A$. Then the Sylow $p$-subgroup of $A$ is normalized by $H$. By Lemma 4.6, $H \leq B'$ for some Borel subgroup $B'$. This is impossible in view of Lemma 4.11. Hence the order of $A$ is not divisible by $p$, and $A$ is a reductive group.

Let us now view $H$ as a subgroup of $GL(V)$ where $V$ is a finite dimensional vector space over an algebraically closed field and $\dim V = 3$ (if $G = PSL_2(q)$, $q \neq 2^n$), $\dim V = 2$ (if $G = SL_2(2^n)$), $\dim V = 8$ (if $G = PSU_3(q^2)$), $\dim V = 4$ (case $^2B_2$), or $\dim V = 7$ (case $^2G_2$). Then $A$ is diagonalizable in $GL(V)$ and not all irreducible components of the $A$-module $V$ are isomorphic (if $A \neq Z(H)$). Thus there exists a non-trivial homomorphism $\rho: H \to S_k$, $k \leq 3, 2, 8, 4, 7$ which corresponds to permutations of isotypical components (otherwise, $A \leq Z(H)$).

**Case 1.** Let $G = PSL_2(q)$, $q \neq 2^n$. For $q \leq 25$ the statement of the lemma is checked by explicit computer calculations with MAGMA. Let now $q > 25$. Recall that $\sigma = t^2$ or $\sigma = t$ for $\langle t \rangle = T'$, where $T'$ is a split torus in $G$. Since the order of $T'$ is $\geq (q - 1)/2$, the order of $\sigma$ is $\geq (q - 1)/4$. Since $\rho(\sigma)$ lies in $S_3$, we have $\rho(\sigma^n) = 1$ for some $n \leq 3$. Thus $\text{ord} \sigma^n \geq (q - 1)/12 > 2$. Hence $C_G(\sigma^n) = T'$ because
\(\sigma^n\) is a regular semisimple element of \(T'\). Since \(\rho(\sigma^n) = 1\), we have \(\sigma^n \in C_H(A)\).

**Sublemma 4.14.** i) With the above notation, suppose there exists \(h \in H\) such that

1. \(h \in C_H(A)\); 2. \(h \in T'\); 3. \(C_G(h) = T'\). Then \(A \subseteq T'\).

ii) If, in addition, there exists \(a \in A\) such that \(C_G(a) = T'\), then \(N_G(\langle h \rangle) = N_G(A) = N_G(T')\).

**Proof.** The first assertion of the sublemma is obvious: if \(h \in C_H(A)\), then \(a \in C_G(h)\) for any \(a \in A\). The second assertion follows from Lemma 4.10 applied to \(S = A\) and \(S = \langle h \rangle\).

On setting \(h = \sigma^n\), we conclude that \(A \subseteq T'\).

Suppose there exists \(a\) generating \(A\) such that \(C_G(a) = T'\). Then by the above sublemma we have \(N_G(\langle \sigma^n \rangle) = N_G(A) = N_G(T')\). On the other hand, we have \(N_G(T') = N_G(\langle \sigma \rangle)\). (Indeed, the inclusion \(N_G(\langle \sigma \rangle) \subseteq N_G(\langle \sigma^n \rangle)\) is obvious, and the inclusion \(N_G(T') \subseteq N_G(\langle \sigma \rangle)\) follows from the fact that in the groups of Lie rank 1 the generator \(w\) of the Weyl group normalizes \(t \in T\) and hence \(\sigma\).) Thus we conclude that \(N_G(\langle \sigma \rangle) = N_G(A) \geq H\), which contradicts the choice of \(\tau\).

Suppose now there is no \(a \in A\) such that \(C_G(a) = T'\). Then \(A = \langle a \rangle\) is a cyclic subgroup of order 2 (all other elements of \(T'\) are regular). Since the order of \(a\) equals 2, we have \(N_G(A) = C_G(A)\). On the other hand, \(C_G(A) = N_G(T') = N_G(\langle \sigma \rangle)\). Again we get a contradiction since \(\tau\) belongs to \(H \subseteq N_G(A)\) but does not belong to \(N_G(\langle \sigma \rangle)\).

**Case 2.** Let \(G = SL_2(2^m), m > 1\). In this case \(G\) has no centre, any element of \(T' = \langle t \rangle\) is regular, the order of \(t\) equals \(2^m - 1\). Hence the order of \(\sigma^2\) equals \(2^m - 1 > 1\). Therefore we can use the same argument as in the preceding case.

**Case 3.** Let \(G = PSU_3(q^2), q > 3\). In this case the semisimple element \(\sigma = t\) or \(t^{[2]}\). The order of the image of \(\sigma\) in \(PSU_3(q^2)\) is \(\geq q - 1\) (recall that the centre of \(SU_3(q^2)\) is nontrivial if and only if \(q + 1 = 3k\) for some \(k\)). Note that \(\sigma^n\) is a nonregular nontrivial element if and only if \(\sigma^n = \text{diag}(-1, 1, -1)\). Hence if \(n \leq 8\) and \(q > 17\), the order of \(\sigma^n \geq (q - 1)/8 > 2\) and therefore the image of \(\sigma^n\) in \(PSU_3(q^2)\) is a regular element. Thus we may use the same arguments as in the
previous case. Explicit computer calculations with MAGMA prove
the statement for the remaining cases \( q \leq 17 \).

Case 4. Let \( G \) be a Suzuki or a Ree group. Every nontrivial element
of \( T \) is regular if \( G \) is a Suzuki group \([\text{Ca2}]\), and every element of \( T \)
of order greater than two is regular if \( G \) is a Ree group \([\text{KLM}]\). Note
that if \( G \) is a Ree group, then the order of a maximal torus \( T' \) is equal
to \( 3^{2m+1} - 1 \). Hence \( 2 \mid T' \mid, 4 \nmid T' \mid \). The element \( \sigma \) is a generator or
the square of a generator of \( T' \). In particular, \( \sigma \) is not an involution.
So if \( n \) is less than the order of \( \sigma^2 \), then \( \sigma^n \) is a regular element of a
maximal quasisplit torus.

Consider the permutation \( \rho(\sigma) \in S_k \). First suppose \( \rho(\sigma) = 1 \). Ar-

guing as in Case 1, we arrive at a contradiction with the choice of
\( \tau \) whenever we can choose \( a \in A \) such that \( C_G(a) = A \). This is al-
ways possible except for the case where \( G \) is a Ree group and \( A \) is
generated by the (unique up to conjugacy) involution \( a \) of \( G \). But in
this latter case we have \( N_G(A) = C_G(a) = \mathbb{Z}/2 \times PSL_2(3^{2m+1}) \) \([\text{Gor2, Th. 3.33(iv)}]\). Hence \( H \subseteq PSL_2(3^{2m+1}) \), and we are reduced to Case
1.

Thus we may assume \( \rho(\sigma) \neq 1 \). Then the same argument as above
with \( \sigma^n \) replacing \( \sigma \) shows that \( \rho(\sigma^n) \neq 1 \) for every \( n < \text{ord} \sigma^2 \). This
means that the restriction of \( \rho \) to \( \langle \sigma^2 \rangle \) is faithful. But this is impossible
since \( \rho(\sigma^2) \in S_4 \) for the Suzuki groups and the order of \( \rho(\sigma) \) must be
less than or equal to 4. However in this case \( \text{ord} \rho(\sigma^2) = \text{ord} \sigma^2 =
2^{2m+1} - 1 > 4 \). The same situation takes place for the Ree groups:
\( \text{ord} \rho(\sigma^2) = \text{ord} \sigma^2 = (3^{2m+1} - 1)/2 > 12 , \) and therefore \( \rho(\sigma^2) \) cannot
belong to \( S_7 \).

Thus in the Suzuki and Ree groups there are no nontrivial abelian
normal subgroups in \( H \), and hence \( H \) is not solvable.

Lemma 4.13 (and hence Proposition 4.1) are proved. \( \square \)

5. Groups of Lie Type of arbitrary rank over fields of
large characteristic

Theorem 5.1. Let \( G \) be a Chevalley group of rank \( > 1 \) over field
char(\( K \) \( ) \neq 2 , k \neq \mathbb{F}_3 \). Then \( \rho(G) = 2 \).

Proof. We need several lemmas (most of whose statements are inde-
pendent of the characteristic of the ground field).
Lemma 5.2. Let $\Pi = \{\alpha_1, \ldots, \alpha_r\}, r \geq 2$, be a basis of an irreducible root system $R \neq A_2$, where the numbering of the simple roots is as in [Bou] in the case $R \neq E_r$, and $\alpha_2$ and $\alpha_3$ are interchanged in the case $R = E_r$. Denote by $w_c = w_{\alpha_1} \cdots w_{\alpha_r}$ the corresponding Coxeter element. Then $w_c(\alpha_1) > 0$, $w_c(\alpha_1) \notin \Pi$ and $w_c^{-1}(\alpha_2) > 0$, $w_c^{-1}(\alpha_2) \notin \Pi$.

Proof. Let $r = 2$. We proceed case by case.

1. $R = B_2$. We have $\alpha_1 = \epsilon_1 - \epsilon_2$, $\alpha_2 = \epsilon_2$, and

$$w_c(\alpha_1) = \epsilon_1 + \epsilon_2 = \alpha_1 + 2\alpha_2, \quad w_c^{-1}(\alpha_2) = \epsilon_1 = \alpha_1 + \alpha_2.$$ 

2. $R = C_2$. We have $\alpha_1 = \epsilon_1 - \epsilon_2$, $\alpha_2 = 2\epsilon_2$, and

$$w_c(\alpha_1) = \epsilon_1 + \epsilon_2 = \alpha_1 + \alpha_2, \quad w_c^{-1}(\alpha_2) = 2\epsilon_1 = 2\alpha_1 + \alpha_2.$$ 

3. $R = G_2$. Then $\alpha_1 = \epsilon_1 - \epsilon_2$, $\alpha_2 = -2\epsilon_1 + \epsilon_2 + \epsilon_3$. We have

$$w_c(\alpha_1) = \epsilon_3 - \epsilon_2 = 2\alpha_1 + \alpha_2, \quad w_c^{-1}(\alpha_2) = 2\epsilon_3 - \epsilon_2 - \epsilon_2 = 3\alpha_1 + 2\alpha_2.$$ 

Let $r > 3$. Note that our numbering of roots gives $\langle \alpha_1, \alpha_2 \rangle = A_2$. Therefore

(5.1) \hspace{1cm} w_{\alpha_1}(\alpha_2) = \alpha_1 + \alpha_2, \quad w_{\alpha_2}(\alpha_1) = \alpha_1 + \alpha_2,

(5.2) \hspace{1cm} w_{\alpha_1}(\alpha_1 + \alpha_2) = \alpha_2, \quad w_{\alpha_2}(\alpha_1 + \alpha_2) = \alpha_1.

Put $\omega = w_{\alpha_3} \cdots w_{\alpha_r}$. Since $\omega$ has no factors $w_{\alpha_1,2}$, we have

(5.3) \hspace{1cm} \omega^{\pm 1}(\alpha_1,2) > 0.

Moreover,

(5.4) \hspace{1cm} \omega^{\pm 1}(\alpha_1) = \alpha_1, \quad \omega^{\pm 1}(\alpha_2) \notin \langle \alpha_1, \alpha_2 \rangle.

From (5.1)–(5.4) we get

(5.5) \hspace{1cm} \omega^{\pm 1}(\alpha_1 + \alpha_2) = \alpha_1 + \alpha_2 + \ldots \neq \alpha_1 + \alpha_2, \quad \omega^{\pm 1}(\alpha_1 + \alpha_2) > 0.

From (5.5) we get

$$0 < w_c(\alpha_1) = w_{\alpha_1} \omega(\alpha_1 + \alpha_2) \notin \Pi,$$

$$0 < w_c^{-1}(\alpha_2) = w_{\alpha_2} \omega^{-1}(\alpha_1 + \alpha_2) \notin \Pi.$$

$\square$
Lemma 5.3. Let $g = u^{-1} \dot{w}_c^{-1}$, where $w_c$ is the Coxeter element from the previous lemma and $u \in U$. Then there exists $x \in G$ such that $[g, x] = u_{a_1}u_{a_2}u'$, where $u_{a_1} \neq 1, u_{a_2} \neq 1$ are the corresponding root subgroup elements and $u' \in U$ does not contain root subgroups factors of type $u_{a_1}, u_{a_2}$. Moreover, every $u_{a_1} \in U_{a_1}$ can be obtained in such a way.

Proof. Let $R = A_2$. Put $1 \neq x = u'_{a_2} \in U_{a_2}$. Then $\dot{w}_c^{-1}u'_{a_2} \dot{w}_c = u'_{a_1} \in U_{a_1}$ and

$$[g, x] = u^{-1}(\dot{w}_c^{-1}u'_{a_2} \dot{w}_c)uu'_{a_2}^{-1} = (u^{-1}u'_{a_1}u)u'_{a_2}^{-1} = u_{a_1}u_{a_2}u'$$

where $u_{a_1} = u'_{a_1}, u_{a_2} = u'_{a_2}$, and $u' = u'_{a_2}[u'_{a_1}, u]u'_{a_2}^{-1}$ does not contain factors from $U_{a_1}, U_{a_2}$.

On varying $x = u'_{a_2}$, we can get an arbitrary $u_{a_1}$.

Let now $R \neq A_2$. We use Lemma 5.2. Put $x = u'_{a_2}u'_{\beta}$ where $\beta = w_c(\alpha_1)$. Then $\dot{w}_c^{-1}u'_{a_2} \dot{w}_c = u'_{\gamma}, \gamma > 0, \gamma \notin \Pi, \dot{w}_c^{-1}u'_{\beta} \dot{w}_c = u'_{a_1} \in U_{a_1}$, and

$$[g, x] = u^{-1}(\dot{w}_c^{-1}u'_{a_2}u'_{\beta} \dot{w}_c)uu'_{a_2}^{-1}u'_{a_2}^{-1} = (u^{-1}u'_{a_1}u)u'_{a_2}^{-1} = u_{a_1}u_{a_2}u'$$

with $u'$ as required. \qed

Lemma 5.4. Let $g = u^{-1} \dot{w}_c^{-1}$, where $w_c$ is the Coxeter element from Lemma 5.2. Then there exists $y \in G$ such that $[g, y] = u_{-\alpha_1}u'$ where $u_{-\alpha_1} \in U_{-\alpha_1}, u' \in U$. Moreover, every $u_{-\alpha_1} \in U_{-\alpha_1}$ can be obtained in such a way.

Proof. Put $y = u_{-\alpha_1}^{-1}$. We have $\dot{w}_c^{-1}u_{-\alpha_1}^{-1} \dot{w}_c = u_{\beta}, \beta > 0$, and $\beta \neq \alpha_1$ (this follows from the definition of $w_c$). Then

$$[g, y] = u^{-1}\dot{w}_c^{-1}u_{-\alpha_1}^{-1} \dot{w}_c uu_{-\alpha_1} = u^{-1}(\dot{w}_c^{-1}u_{-\alpha_1} \dot{w}_c)uu_{-\alpha_1} = u^{-1}u_{\beta}^{-1} uu_{-\alpha_1} = u_{-\alpha_1}(u_{\alpha_1}^{-1}u_{\beta}^{-1} uu_{-\alpha_1}) = u_{-\alpha_1}u'.$$

The last equality follows from the fact that $u_{\alpha_1}^{-1}u_{\beta}^{-1} u$ belongs to the unipotent radical of the minimal parabolic subgroup corresponding to the root $\alpha_1$. \qed

Lemma 5.5. Let $P = LV$ be a parabolic subgroup of a Chevalley group $G$ where $L$ is a Levi factor and $V$ is the unipotent radical of $P$. Further, let $x_1, \ldots, x_s, g \in P$, and let $\bar{x}_1, \ldots, \bar{x}_s, \bar{g}$ be their images in $L/Z(L)$ with respect to the natural homomorphism $P \to L \to L/Z(L)$. If the group $\langle [g, \bar{x}_1], \ldots, [g, \bar{x}_s] \rangle$ is not solvable, then the group $\langle [g, x_1], \ldots, [g, x_s] \rangle$ is not solvable too.
Lemma 5.6. Let $G$ be a quasisimple Chevalley group of rank one $\neq A_1(2^m)$. Then there exist $u_1 \in U^-, u_2 \in U^+$ such that $\langle u_1, u_2 \rangle$ is not solvable.

Proof. The proof immediately follows from Dickson’s lemma (see [Gor2, Theorem 2.8.4] and [Nu]), where there are exhibited explicit pairs of unipotent elements $u_1 \in U^-, u_2 \in U^+$ such that the subgroup $\langle u_1, u_2 \rangle$ is not solvable. □

Now we are able to finish the proof of the theorem. Let $X \subset \Pi$, and let $X = X_1 \cup \ldots \cup X_l$ be the decomposition of $X$ into a disjoint union of subsets $X_i$ generating irreducible subsystems of $R$. Put

$$w_{X_i} = \prod_{\alpha \in X_i} w_\alpha$$

where the product is taken in any order. Set

$$w_X = \prod_i w_{X_i}.$$  

(If $X = \emptyset$, we set $w_X = 1$.) Then $w_X$ is a generalized Coxeter element (see [GS]) corresponding to $X$. Denote $\tilde{W}_X = \langle \tilde{w}_\alpha, \alpha \in \langle X \rangle \rangle$, where $\langle X \rangle$ stands for the root system generated by $X$.

Let $g \in G \setminus Z(G)$. Since $\text{char}(K) \neq 2$, $G$ is not of type $^2F_4$, and according to [GS, Proposition 6], the conjugacy class of $g$ intersects a generalized Coxeter cell $B\tilde{w}_XB$ for some $X$.

Remark 5.7. For $G = ^2F_4$ it is not known whether the above statement is true or not.

Thus we may assume

$$g = u\tilde{w}_X, \quad u \in U.$$  

To finish the proof of Theorem 5.1, we now consider three separate cases. (Note that if $X \neq \emptyset$, we have $|X_i | \neq 0$ for every $i$.)

Case 1. Suppose $X = \emptyset$. Then $g = uh, u \in U, h \in T$. We may assume $u \neq 1$ (otherwise we can conjugate $g$ with an appropriate element from $U$). Conjugating $g$ with an appropriate element $\tilde{w}$ we can get an element $g' = u'h'$ in the conjugacy class of $g$ such that
\[
u' \in U \text{ and among root factors of } u' \text{ there is a simple root subgroup factor } u_{\alpha_i}.
\]

Indeed, let
\[
u = \prod_{\alpha \in M \subset R^+} u_{\alpha}, \ u_{\alpha} \neq 1.
\]

Let \( k = \min\{ht(\alpha) \mid \alpha \in M\} \). Then there exists an element \( w \in W \) such that \( 0 < \min\{ht(\alpha) \mid \alpha \in w(M)\} < k \). Thus we can get \( \min\{ht(\alpha) \mid \alpha \in w(M)\} = 1 \) for an appropriate \( w \in W \).

Put \( P = T(U_{\pm \alpha_i})U = B(w_{\alpha_i})B \). Now in the parabolic subgroup \( P \) we can take the Levi factor \( L_i \) of rank 1 corresponding to the root \( \alpha_i \).

Applying Lemma 5.5 and Proposition 4.1 to \( L_i \), we get the result.

**Case 2.** Suppose \( |X_i| = 1 \) for some \( i \). Let \( P = B\hat{W}_X B \). Then there exists a simple component \( L_i \) of a Levi factor of \( P \) which is of rank one. Then we can use Lemma 5.5 and Proposition 4.1.

**Case 3.** Suppose \( |X_i| > 1 \) for every \( i \). Put \( P = B\hat{W}_X B \). Consider the group \( L_i = T(U_{\pm \alpha} \mid \alpha \in \langle X_i \rangle) \). This is a subgroup of a Levi factor \( L = T(U_{\pm \alpha} \mid \alpha \in \langle X \rangle) \) of \( P \). Let \( g_i = u_i w_{X_i} \) be \( i \)th component of \( g \). We may assume that the order of simple reflections in (5.6) corresponds to the order in Lemmas 5.2–5.4. Then by Lemmas 5.3–5.4, we have
\[
[g_i, x] = u_{\alpha_1} u'', [g_i, y] = u_{-\alpha_1} u'.
\]

It remains to use Lemmas 5.5–5.6. \( \square \)

6. **Groups of Lie type over fields of small characteristic**

**Proposition 6.1.** Let \( G \) be a nonsolvable Chevalley group over a field \( K \) where either \( \text{char}(K) = 2 \) or \( K = \mathbb{F}_3 \). Then \( \rho(G) \leq 3 \).

*Proof.* Throughout this section we assume \( G \neq 2F_4(q^2) \) leaving this case for separate consideration in the next section.

We have to prove that for every \( g \notin Z(G) \) one can find \( x_1, x_2, x_3 \in G \) such that the group \( F = \langle [g, x_1], [g, x_2], [g, x_3] \rangle \) is not solvable.

By Proposition 4.1, for any nonsolvable rank 1 group \( G \) we have \( \rho(G) = 2 \). Thus we may and shall assume that rank \( G > 1 \).
First suppose char($K$) = 2, | $K$ | > 2. We use the same case-by-case subdivision as in the proof of Theorem 5.1 above. Cases 1 and 2 are treated in exactly the same way (two commutators are enough). Suppose that we are in the conditions of Case 3, i.e. | $X_i$ | > 1 for every $i$. Arguing as in the proof of Theorem 5.1, we reduce to the case of $L_i/Z(L_i)$, where $L_i$ is a Levi factor of semisimple rank 1. If $L_i$ is not of type $A_1(2^m)(m > 1)$, we can use the same arguments as in Lemma 5.6 (once again, two commutators are enough). So we may and shall assume $G$ of type $A_1(2^m)(m > 1)$.

Arguing as in the proofs of Lemmas 5.3–5.4, we conclude that there exist $x_1, x_2, x_3 \in G$ such that $[g, x_1] = v \in U^-$, $[g, x_2] = u' \in U$, $[g, x_3] = u \in U$, $u \notin \langle u' \rangle$, where $v$, $u'$, $u$ are arbitrary given elements. Moreover, according to [EG1], [CEG], we can arrange our choice so that to make $s = vu$ a generator of a maximal split torus of $G$. Finally, note that $u$ is a regular unipotent element (as all unipotent elements in $SL_2(2^m)$).

Put $\sigma = s$, $\tau = u$. Since $v, u'$ are involutions, $u'$ belongs to $N_G(\langle \sigma \rangle)$. Indeed, we have $u'\sigma u'^{-1} = u'\sigma u' = u'su' = u'vu'u' = u'u = (vu')^{-1} = \sigma^{-1}$. Then $\tau = u$ does not belong to $N_G(\langle \sigma \rangle)$ (otherwise we would have $u, u' \in N_G(\langle \sigma \rangle)$ and $| \langle u, u' \rangle | = 4$, contradiction to $| N_G(\langle \sigma \rangle) | = 2(2^m - 1)$). Further, $u$ and $vu'$ cannot be in the same parabolic subgroup ($u$ can belong only to $B$ (Lemma 4.5), but $vu' \notin B$). Now we can repeat the arguments used in the proof for rank one groups over a field of odd characteristic (see Lemmas 4.11 and 4.13).

Let now | $K$ | = 2 or | $K$ | = 3.

Case 1. $X = \emptyset$. Then $g = uh$, $u \in U$, $h \in T$. We may assume $u \neq 1$ (otherwise we can conjugate $g$ with an appropriate element from $U$). Conjugating $g$ with an appropriate element $\tilde{w}$, we can get $g' = u'h'$ in the conjugacy class of $g$ such that $u' \in U$ and among root factors of $u'$ there is a nontrivial simple root subgroup factor $u_{\alpha_i}$ (see Case 1 in the end of the proof of Theorem 5.1). Let $\alpha_j$ be any root adjacent (in the Dynkin diagram) to $\alpha_i$. Then we can reduce to the case of a Levi factor of semisimple rank 2, as above. For all groups of rank 2 over $\mathbb{F}_2$ and $\mathbb{F}_3$ we use explicit MAGMA computations (see Table 1).

Case 2. | $X_i$ | = 2 for some $i$. Let $P$ be a parabolic subgroup, $P = BW_XB$. Then there exists a simple component $L_i$ of a Levi
factor of $P$ which is of semisimple rank two. Then we can use Lemma 5.5 and explicit MAGMA computations for the groups of rank two (see Table 1).

**Case 3.** \(|X_i| > 2\) for some \(i\).

In this case, the arguments based on the use of Lemmas 5.3–5.4 are not enough. Instead we shall use the following more subtle version of Lemma 5.4.

**Lemma 6.2.** Let \(g = u^{-1}w_c^{-1}\), where \(w_c\) is the Coxeter element from Lemma 5.2. Then:

1) there exists \(y \in G\) such that \([g, y] = u_{-\alpha_1}u'\) where \(u_{-\alpha_1}\) is any prescribed element from \(U_{-\alpha_1}\) and \(u' \in U\);

2) there exists \(z \in G\) such that \([g, z] = fu''\) where \(f \in \langle U_{\alpha_2}, U_{-\alpha_2} \rangle\), \(f \notin B\) and \(u'' \in U\).

**Proof.** 1) See Lemma 5.4.

2) Recall that \(w_c = w_{\alpha_1} \cdots w_{\alpha_r} w_{\alpha_2} = \omega \omega_{\alpha_2}\). Since \(\omega\) does not contain the factor \(w_{\alpha_2}\), we have \(\omega(\alpha_2) = \gamma > 0\) and \(w_c^{-1}(\gamma) = w_{\alpha_2}^{-1}(\gamma) = w_{\alpha_2}(\alpha_2) = -\alpha_2\). Put \(z = u_\gamma \in U_\gamma, u_\gamma \neq 1\). Then \(w_c^{-1}z w_c = u_{-\alpha_2} \in U_{-\alpha_2}\). Further, for every \(0 < \beta \neq \alpha_2\) either \(\beta + (-\alpha_2)\) is not a root or \(\beta + (-\alpha_2) \in R^+\). Hence \(u_\beta u_{-\alpha_2} u_\beta^{-1} = u_{-\alpha_2} v\) for some \(v \in U\). Also, for every \(u'_{\alpha_2} \in U_{\alpha_2}\)

\[u'_{\alpha_2} u_{-\alpha_2} u'_{\alpha_2}^{-1} \in \langle U_{-\alpha_2}, U_{\alpha_2} \rangle\quad \text{and} \quad u'_{\alpha_2} u_{-\alpha_2} u'_{\alpha_2}^{-1} \notin B.\]

Recall that \(g = u^{-1}w_c^{-1}\). We may assume \(u = vu'_{\alpha_2}\) where the element \(v \in U\) does not have factors from \(U_{\alpha_2}\). We have

\[\begin{align*}
[g, z] &= u'_{\alpha_2}^{-1} v^{-1}(w_c^{-1} u_\gamma w_c) v u'_{\alpha_2} u_\gamma^{-1} = u'_{\alpha_2}^{-1} v^{-1} u_{-\alpha_2} v u'_{\alpha_2} u_\gamma^{-1} \\
&= u'_{\alpha_2}^{-1} u_{-\alpha_2} u'_{\alpha_2} v' u_\gamma^{-1}
\end{align*}\]

for some \(v' \in U\). Put \(f = u'_{\alpha_2}^{-1} v^{-1} u_{-\alpha_2}\) and \(u'' = v' u_\gamma^{-1}\). We have

\[\begin{align*}
[g, z] &= fu''
\end{align*}\]

where \(f \in \langle U_{\alpha_2}, U_{-\alpha_2} \rangle, f \notin B\) and \(u'' \in U\). \(\square\)

By Lemmas 5.2–5.6, we can come up with the situation when \(\Gamma \leq G\) corresponds to the root system generated by \(\alpha_1, \alpha_2\) (in our notations), i.e., \(\Gamma\) is of type \(A_2\) (here \(\Gamma\) denotes the Levi factor of the corresponding
parabolic subgroup of $G$). By Lemmas 5.3 and 6.2, we have got the following elements in $\Gamma$ (which are images of commutators of $G$):
\[ v_1 = u_{-\alpha_1}v', \quad v_2 = fu''u', \quad u = u_{\alpha_1}u_{\alpha_2}u', \]
where $1 \neq u_{-\alpha_1} \in U_{-\alpha_1}$, $v' \in U_\Gamma := \langle U_{\alpha_1}, U_{\alpha_2} \rangle$, $f \in \langle U_{-\alpha_2}, U_{\alpha_2} \rangle$, $f \notin B$, $v'' \in U_\Gamma$, $1 \neq u_{\alpha_1} \in U_{\alpha_1}$, $1 \neq u_{\alpha_2} \in U_{\alpha_2}$, $u' \in U_{\alpha_1+\alpha_2}$.

We have to show that the group $\langle v_1, v_2, u \rangle$ is not solvable. Consider the groups
\[ P = \langle v_1, u \rangle \leq \bar{P} = \langle u_{-\alpha_1}, U_\Gamma \rangle, \quad P' = \langle v_2, u \rangle \leq \bar{P}' = \langle u_{-\alpha_2}, U_\Gamma \rangle \]
and the natural homomorphisms
\[ \theta: \bar{P} \to \bar{P}/R_u, \quad \theta': \bar{P}' \to \bar{P}'/R'_u \]
where $R_u$ (resp. $R'_u$) is the unipotent radical of $\bar{P}$ (resp. $\bar{P}'$). We have
\[ \theta(\bar{P}) = \bar{P}/R_u \cong SL_2(p), \quad \theta'(\bar{P}') = \bar{P}'/R'_u \cong SL_2(p) \]
where $p = 2, 3$. Obviously, $\langle u_{-\alpha_1}, u_{\alpha_1} \rangle \cong SL_2(p)\langle f, u_{\alpha_2} \rangle \cong SL_2(p)$ if $p = 2, 3$. Hence
\[ \theta(P) = \langle u_{-\alpha_1}, u_{\alpha_1} \rangle \cong SL_2(p), \quad \theta'(P') = \langle f, u_{\alpha_2} \rangle \cong SL_2(p), \quad p = 2, 3. \]

Let us show that
\[ \text{Ker } \theta \cap P \neq 1, \quad \text{Ker } \theta' \cap P' \neq 1. \]
Recall that $u$ is regular, so if $|K| = 2$, then $u^2 \in U_{\alpha_1+\alpha_2}$, and thus the order of $u$ equals 4. Hence $u^2 \in \text{Ker } \theta \cap P$ ($u^2 \in \text{Ker } \theta' \cap P'$). Let now $|K| = 3$. Take $h \in P$ (or $h \in P'$) such that $\theta(h)$ (or $\theta'(h)$) equals $\text{diag}(-1, -1) \in SL_2(3)$. Then explicit matrix calculations show that $[h, u] = u_{\alpha_2}u_{\alpha_1+\alpha_2} \in \text{Ker } \theta \cap P$ (or $[h, u] = u_{\alpha_1}u_{\alpha_1+\alpha_2} \in \text{Ker } \theta' \cap P'$).

We proved that $\text{Ker } \theta \cap P$ (resp. $\text{Ker } \theta' \cap P'$) is not trivial. Let us show that $\text{Ker } \theta \cap P = \text{Ker } \theta$ (resp. $\text{Ker } \theta' \cap P' = \text{Ker } \theta'$). Note that $\text{Ker } \theta \cong K^2$ is a 2-dimensional vector $K$-space on which $P$ acts by conjugation. Since $\theta(P) \cong SL_2(p)$, we have only one nonzero orbit of $P$ in $\text{Ker } \theta \cong K^2$. Hence $\text{Ker } \theta \cap P = \text{Ker } \theta \cong K^2$, and therefore $P = \bar{P}$. By the same arguments, $\text{Ker } \theta' \cap P' = \text{Ker } \theta'$ and $P' = \bar{P}'$. Hence
\[ P = \langle v_1, u \rangle = \bar{P} = \langle u_{-\alpha_1}, U_\Gamma \rangle, \quad P' = \langle v_2, u \rangle = \bar{P}' = \langle u_{-\alpha_2}, U_\Gamma \rangle. \]
Thus, $U_\Gamma, u_{-\alpha_1}, u_{-\alpha_2}$ are all contained in $\langle v_1, v_2, u \rangle$, and therefore
\[ \Gamma = \langle v_1, v_2, u \rangle \cong SL_3(p). \]
Case 4. | $X_i | = 1$ for every $i$. Since for all groups of rank one or two the proposition has been checked, we may assume rank $G > 2$.

First suppose that the root system corresponding to $G$ does not contain $D_4$, i.e. is of one of the types $A_r, B_r, C_r, F_4$. Suppose $X_i = \{ \alpha_j \}$, where $j$ is the number of the root in the standard numbering. Note that by construction of $X$, neither $\alpha_{j-1}$, nor $\alpha_{j+1}$ belong to $X$.

Suppose that $\alpha_{j+2} \notin X$ or $\alpha_{j-2} \notin X$ (in particular, this assumption holds if $\alpha_{j \pm 2}$ does not exist). Then the subgroup $L$ of $G$ generated by $U_{\pm \alpha_j}$ and $U_{\pm \alpha_{j+1}}$ (or $U_{\pm \alpha_{j-1}}$) commutes with the elements $U_{\pm \beta}$ for every $\beta \in X \setminus X_i$. Thus we are reduced to the group $L$ of rank two, and the statement is proved. Let us now suppose that $\alpha_{j+2} \in X$.

Then we can consider the group $L = \langle U_{\pm \alpha_j}, U_{\pm \alpha_{j+1}}, U_{\pm \alpha_{j+2}} \rangle$ which commutes with every $U_{\pm \beta}, \beta \in X \setminus (X_i \cup \{ \alpha_{j+2} \})$. Hence we may assume rank $G = 3$ and $g = w_{\alpha_1} w_{\alpha_3} u$ for some $u \in U$. Here we have to check the groups $A_3(p), B_3(p), C_3(p), 2D_4(p), 2A_5(p), 2A_6(p)$, $p = 2, 3$. We can exclude $2D_4(p), 2A_5(p), 2A_6(p)$, $p = 2, 3$, because these groups have a root subgroup $G_\alpha, \alpha = \alpha_1$ or $\alpha = \alpha_3$, which is isomorphic to $SL_2(p^2)$, and we can use our considerations for rank one. Since $A_3(2) \cong A_8, B_3(2) \cong C_3(2)$, it remains to calculate in the groups $A_3(3), B_3(2), B_3(3), C_3(3)$. These groups are checked by explicit MAGMA calculations (see Table 1).

Suppose now that the root system of $G$ is of type $D_r$ or $E_r$. Let $\beta$ be the root corresponding to the node with 3 edges on the Dynkin diagram. First suppose $\beta \in X$. Then we can take $\gamma \in \Pi$ which is joined with $\beta$ and disjoint from all other roots. As $\beta \in X$, we have $\gamma \notin X$, and $L = \langle U_{\pm \beta}, U_{\pm \gamma} \rangle$ commutes with every $U_{\pm \delta}, \delta \notin \beta, \delta \in X$. Thus we may reduce our considerations to groups of rank 2. Let now $\beta \notin X$. Suppose $r > 4$. If none of $\alpha_1, \alpha_2$ belongs to $X$, we are reduced to the case of type $A_2$ treated above. If not, we are reduced to the case of groups of rank 1. So it remains to consider the case $r = 4$, i.e., the case of the groups $D_4(p), p = 2, 3$. This is checked by MAGMA (see Table 1).

7. Groups $^2F_4(q^2)$

Recall that in light of Remark 5.7 we have to consider the groups of type $^2F_4(q^2)$ separately.

If $R$ is a root system and $G_R$ is a connected reductive algebraic group with root system $R$ defined over some algebraically closed field,
we denote by $\tilde{G}_R$ the universal cover of the derived group of $G_R$. If it is clear what is the root system under consideration, we often drop the subscript $R$. In particular, throughout this section we denote by $G$ the twisted Chevalley group $F_4(q^2)$, $q = \sqrt{2^{2m+1}}$, and by $\tilde{G}$ the simple algebraic group of type $F_4$ defined over $F_2$ (identifying it with its group of $F_2$-points). We have $G \subset \tilde{G}$. Correspondingly, tilde always indicates to subgroups of $\tilde{G}$. We denote $K = F_{q^2}$.

**Theorem 7.1.** Let $G = F_4(q^2)$. Then $\rho(G) = 2$.

**Proof.** For $m = 0$, the group $G$ is not simple; its derived subgroup (the Tits group) is checked by MAGMA (see Table 1). So throughout below we assume $m > 0$.

Let $1 \neq g \in G$. First suppose $g \in P$ for some parabolic subgroup $P$. Any parabolic subgroup is conjugate to a standard parabolic subgroup (see [Ca2]). We may thus assume $P$ to be a standard parabolic subgroup. We have $P = LV, V = R_u(P)$. We may assume that the image of $g$ in $P/Z(L)V$ is not trivial (as above) and reduce the consideration to the group $L/Z(L)$ of semisimple rank 1.

Hence we may assume that $g$ does not belong to any parabolic subgroup $P$. Then (see [Ca2, 6.4.5]) the order of $C_G(g)$ is prime to $p = 2$ (and so is an odd number). Hence $g$ is a regular semisimple element, and by [Gow] we can get representatives of any two semisimple conjugacy classes of $G$ in the form $\sigma = [g, x], \tau = [g, y]$.

Put $H = \langle \sigma, \tau \rangle$. Suppose $H$ is solvable. Denote by $I = \{p_1, \ldots, p_k\}$ some set of prime divisors of $|H|$ and by $H_I$ a Hall subgroup of $H$ corresponding to $I$. Let $A$ be a maximal normal abelian subgroup of $H_I$.

Let us now consider two separate cases: $m \geq 2$ and $m = 1$.

*General case* $q = \sqrt{2^{2m+1}}, m \geq 2$.

We have [Ca2, 2.9, p. 76]

$$|G| = q^{24}(q^2 - 1)(q^6 + 1)(q^8 - 1)(q^{12} + 1) = (q^2)\cdot(q^2 - 1)^2(q^2 + 1)^2((q^2)^2 + 1)^2((q^2)^2 - q^2 + 1)((q^2)^4 - (q^2)^2 + 1),$$

where $q = \sqrt{2^{2m+1}}$. 
Lemma 7.2. Let $T$ be a maximal quasisplit torus of $G$. Then there exists $t \in T$ such that $t$ is a regular element of $\tilde{G}$, i.e. $C_{\tilde{G}}(t) = \tilde{S}$ is a maximal torus in $\tilde{G}$.

Proof. Let $\tilde{S}$ be a maximal torus of $\tilde{G}$ containing $T$. Let $\alpha$ be a positive root of $R = F_4$ corresponding to $\tilde{S}$, and let $\alpha_T: T \to \mathbb{F}_2$ be the restriction of $\alpha$ to $T$.

Let us show that

\begin{equation}
\text{Im } \alpha_T = K^* \tag{7.1}
\end{equation}

for every $\alpha \in R(F_4)$. We have the following simple root system

$\alpha_1 = \epsilon_2 - \epsilon_3, \alpha_2 = \epsilon_3 - \epsilon_4, \alpha_3 = \epsilon_4, \alpha_4 = \frac{1}{2}(\epsilon_1 - \epsilon_2 - \epsilon_3 - \epsilon_4),$

and

$T = (h_1(t) = h_{\alpha_1}(t)h_{\alpha_4}(t^\theta), \ h_2(s) = h_{\alpha_2}(s)h_{\alpha_3}(s^\theta))$

where $s, t \in K^*, 2\theta^2 = 1$. Further,

$\epsilon_1(h_1(t)) = t^\theta, \epsilon_2(h_1(t)) = t^{1-\theta}, \epsilon_3(h_2(s)) = s, \epsilon_4(h_1(t)) = t^{-\theta}$

(note $2(1 - \theta)(1 + \theta) = 2 - 2\theta^2 = 2 - 1 = 1$),

$(\epsilon_1 + \epsilon_2)(h_1(t)) = t, (\epsilon_1 - \epsilon_2)(h_1(t)) = t^{1-2\theta}$

$((1 - 2\theta)(1 + 2\theta) = 1 - 4\theta^2 = 1 - 2 = -1)$,

$(\epsilon_1 \pm \epsilon_3)(h_2(s)) = s^{\pm 1}, (\epsilon_1 \pm \epsilon_4)(h_2(s)) = s^{\pm 1 + 2\theta},$

$(\epsilon_2 \pm \epsilon_3)(h_2(s)) = s^{\pm 1}, (\epsilon_2 \pm \epsilon_4)(h_2(s)) = s^{\pm 1 + 2\theta},$

$(\epsilon_3 + \epsilon_4)(h_2(s)) = s^{2\theta}, (\epsilon_3 - \epsilon_4)(h_2(s)) = s^{2-2\theta},$

$\frac{1}{2}(\epsilon_1 \pm \epsilon_2 \pm \epsilon_3 \pm \epsilon_4)(h_2(s)) = s^{\pm 1 + \theta}$ or $s^{\pm \theta}$. 

Thus we have (7.1). From (7.1) we get

$\mid \text{Ker } \alpha_T \mid = (q^2 - 1)$

and

\begin{equation}
\mid \bigcup_{\alpha \in R^+(F_4)} \text{Ker } \alpha_T \mid < (q^2 - 1) \cdot 24 < (q^2 - 1)^2. \tag{7.2}
\end{equation}

From (7.2) we conclude that the set $M = T \setminus \bigcup_{\alpha \in R^+(F_4)} \text{Ker } \alpha_T$ is not empty. Any element $t \in M$ is regular. The lemma is proved. $\square$

Lemma 7.3. There exists a prime $p \neq 2, 3, (p, q^2 - 1) = 1$ such that $p \mid q^2 + 1$ or $p \mid q^4 + 1$. 

Proof. This follows from the fact that \((q^2 - 1, q^2 + 1) = 1\) and \((q^2 + 1, q^4 + 1) = 1\). \(\square\)

**Lemma 7.4.** Let \(R\) be a root system, and let \(G_R\) be a connected reductive group. Further, let \(A \subseteq G_R\) be a finite abelian subgroup consisting of semisimple elements and such that \(\langle |A|, |W(R)| \rangle = 1\). Then there exists a maximal torus \(S\) in \(G_R\) such that \(A \subseteq S\).

Proof. Let \(G_R = S'G_{R}', \) where \(S' \leq Z(G_R)\) is a torus of \(G_R\) and \(G_{R}'\) is semisimple. Hence \(Z(G_R) = S'A'\), where \(A' = Z(G_{R}')\) is a finite abelian group. Suppose \(A \subseteq Z(G_R)\). Since \(\langle |A|, |W(R)| \rangle = 1\), we have \(\langle |A|, |A'| \rangle = 1\) (because \(|W(R)|\) is divisible by \(|A'|\)), and hence \(A \subseteq S'\). Suppose \(a \notin Z(G)\) for some \(a \in A\). Let \(S\) be a maximal torus of \(G_R\) containing \(a\). By [Ca2, Theorem 3.5.3], we have

\[
C_{G_R}(a) = \langle S, U_\alpha, \hat{w} \mid \alpha(a) = 1, w \in C_{W(R)}(a_1) \rangle,
\]

\[
C_G(a_1)^0 = \langle T_1, U_\alpha, \mid \alpha(a) = 1 \rangle.
\]

Hence \(|C_G(a)/C_G(a)^0|\) divides \(|W(R)|\), and therefore \(A \subseteq C_G(a)^0 \neq G_R\). To finish the proof, we use induction by \(|R|\). \(\square\)

Before going over to the proof of the assertion of the theorem, we shall describe some general construction (parallel to that of Lemma 4.10).

Let \(G_R\) be a connected semisimple group corresponding to a root system \(R\), and let \(S\) be a maximal torus of \(G_R\). Further, let \(M \subseteq S\), let \(g \in N_{G_R}(M)\), and let \(g = uwv\) be a Bruhat decomposition of \(g\) in \(G_R\) with respect to a Borel subgroup containing \(S\). We may assume \(wvw^{-1} \in U^-.\) Let \(s \in M\). Then

\[
gsg^{-1} = wvsv^{-1}w^{-1}u^{-1} = uw(s)v'u^{-1} = s' \in M \subseteq S,
\]

where \(v' \in U^-\). Hence \(w(s)v' = u^{-1}s'u = s'[s^{-1}, u^{-1}]\). Since \([s^{-1}, u^{-1}] \in U, v' = [w(s)^{-1}, v] \in U^-\), we have \([s^{-1}, u^{-1}] = 1, [w(s)^{-1}, v] = 1, s' = w(s)\). Since we can consider any \(s \in M\), we have \(u, v \in C_{G_R}(M)\). Now we have a homomorphism

\[
\phi: N_{G_R}(M) \to W(R)
\]

with

\[
(7.3) \quad \text{Ker}\phi = Z_{G_R}(M).
\]
We can now go over to the proof of Theorem 7.1.

Set $\sigma = t$, where $t$ is chosen as in Lemma 4.11. Let $\tau$ be an element of order $p$ (it exists by Lemma 7.3). Denote by $I$ the set consisting of $p$ and all prime divisors of $q - 1$. Since all Hall subgroups $H_I$ are conjugate and each element of order $p$ belongs to one of those, we may assume $t \in H_I$ and some element $\tau'$ of order $p$ is also in $H_I$.

Note that $2, 3 \mid (q^2 - 1)$. Since $|W(F_4)| = 2^73^2$, we have $\sigma, \tau' \in C_G(A)^0$ (by (7.3) and Lemma 7.4). Then $A \subseteq T \subseteq \bar{T}$ where $\bar{T}$ is the unique maximal torus of $\bar{G}$ containing $T$ (recall that $T$ contains a regular semisimple element of $\bar{G}$).

Denote by $R \subset R(F_4)$ the minimal (with respect to inclusion) root subsystem such that

$$\sigma, \tau' \in G_R = \langle \bar{T}, U_\alpha \mid \alpha \in R \rangle.$$

First note that $R \neq R(F_4)$ because otherwise we would have $A \subseteq Z(F_4) = 1$ (recall that $H \leq C_G(A)^0$). Second, note that $R \neq \emptyset$ because $\tau' \notin T = \bar{T}^F$. Set $G'_R = \langle U_\alpha \mid \alpha \in R \rangle$. Then $G_R = SG'_R$ where $S \leq \bar{T} \cap Z(G_R)$ is a subtorus of $\bar{T}$. Then $Z(G_R) = SZ(G'_R)$.

Since the orders of $\sigma, \tau'$ are prime to 2, 3, we have $\sigma, \tau' \notin Z(G'_R)$, and hence so are the orders of their images $\bar{\sigma}, \bar{\tau}'$ in $\overline{G'_R} = G'_R/(Z(G'_R) \cap S)$. Now we have a semisimple group $\overline{G'_R}$ with a maximal torus $\overline{T} = \bar{T}/S$ which contains the solvable group $H_I = \langle \bar{\sigma}, \bar{\tau}' \rangle \neq 1$, where $\bar{\sigma} \in \overline{T}$ is a regular element. Let $A_1$ be a maximal abelian normal subgroup of $\overline{H_I}$. Then $A_1 \subseteq \overline{T}$ and $A_1 \not\subseteq Z(\overline{G'_R})$ (note that 2, 3 are the only primes dividing both $|W(R)|$ and $Z(\overline{G'_R})$). By (7.3), we have

$$\bar{\sigma}, \bar{\tau}' \in C_{\overline{G'_R}}(A_1)^0 = \langle \overline{T}, U_\beta \mid \beta(A_1) = 1 \rangle = \langle \overline{T}, U_\beta \mid \beta \in R' \not\subseteq R \rangle.$$

Hence

$$\sigma, \tau' \in \langle \bar{T}, U_\beta \mid \beta \in R' \rangle.$$

This is a contradiction with the choice of $R$.

Let us now consider the last remaining special case.

Case $q = \sqrt{23}$.

Here $|G| = 2^{36} \cdot 3^5 \cdot 5^2 \cdot 7^2 \cdot 13^2 \cdot 19 \cdot 37 \cdot 109$. 
Let $|\langle \sigma \rangle| = 109$, $|\langle \tau \rangle| = 37$, and let $H_0 \subseteq H$ be a Hall subgroup of $H$ of order $37 \cdot 109$. Since $(37, 109 - 1) = 1$, the group $H_0 = \langle h \rangle$ is cyclic of order $37 \cdot 109$.

Let, as above, $\tilde{G}$ denote the simple algebraic group of type $F_4$ over the field $\mathbb{F}_2$, and let $F$ be the Frobenius map of $G$ such that $G = \tilde{G}^F$. Since $h \in \tilde{G}^F$, the centralizer $C_{\tilde{G}}(h)$ is an $F$-stable connected reductive group ([Ca2, 3.5.6]) which, in turn, contains an $F$-stable maximal torus $\tilde{T}$ (which is also a maximal torus of $\tilde{G}$). Hence $h \in \tilde{T}$. But

$$|\tilde{T}^F| = \prod_{i=1}^{4}(q - \epsilon_i)$$

where each $\epsilon_i$ is a root of unity [Ca2, 3.3.5]. Since

$$|q - \epsilon_i| \leq q + 1 = \sqrt{8} + 1 \leq 4,$$

we conclude that $|\tilde{T}^F| \leq 256 < 37 \cdot 109$. Contradiction.

The theorem is proved. \qed

8. GROUPS GENERATED BY 3-TRANSPOSITIONS

In this section we show that the estimate of Proposition 6.1 is sharp as follows from the case of groups generated by 3-transpositions (see [Fi], [As] for definitions and notations).

**Definition 8.1.** [Fi] Let $G$ be a finite group generated by a class $D$ of conjugate involutions such that any pair of non-commuting elements of $D$ generates a dihedral group of order 6; then $D$ is a class of conjugate 3-transpositions of $G$.

Equivalently, the product of any two involutions from $D$ is of order 1, 2, or 3.

**Proposition 8.2.** Let $G$ be a finite group generated by a class $D$ of conjugate 3-transposition. Then any element of $D$ is 2-radical.

**Proof.** Let $y \in D$, $x_1, x_2 \in G$. Denote $a = [y, x_1]$, $b = [y, x_2]$, $H = \langle a, b \rangle$. We have to prove that $H$ is solvable.

Since $|y| = 2$, both $a$ and $b$ are products of two elements of $D$ and hence are of order 1, 2, or 3.
(i) If any of them is of order 1, then \( H \) is cyclic. If they are both of order 3, then \( H \) is a subgroup of the group generated by all elements of \( D \) of order 3, and this latter group is solvable [Fi, Cor. 1.6].

(ii) Suppose that both \( a \) and \( b \) are of order 2. Then we have \( ab = a^{-1}b = x_1y_1^{-1}y \cdot yx_2y_2^{-1} = x_1y_1^{-1} \cdot x_2y_2^{-1} \). So \( ab \) is a product of two elements of \( D \) and is thus of order 1, 2, or 3. If \( |ab| = 1 \), then \( a = b \), and \( H \) is cyclic of order 2. If \( |ab| = 2 \), then \( H \) is the Klein four-group. If \( |ab| = 3 \), then \( H \cong S_3 \). In all the cases \( H \) is solvable.

(iii) Finally, suppose that \( |a| = 2 \), \( |b| = 3 \). Then we have, as above, \( ab = a^{-1}b = x_1y_1^{-1} \cdot x_2y_2^{-1} \), and \( ab \), as a product of two elements of \( D \), is of order 1, 2, or 3. The case \( |ab| = 1 \) cannot occur. If \( |ab| = 3 \), then \( H = \langle ab, b \rangle \) is generated by elements of order 3 and is thus solvable, as in (i). If \( |ab| = 2 \), then \( H \cong S_3 \). Again, in all the cases \( H \) is solvable.

\[ \square \]

Corollary 8.3. Let \( G \) be one of the following groups:

- a symmetric group \( S_n \);
- a symplectic group \( Sp(2n, 2)(n \geq 2) \);
- an orthogonal group \( O^\mu(2n, 2) \) for \( \mu \in \{-1, 1\} \) and \( n \geq 2 \);
- a unitary group \( PSU(n, 2)(n \geq 4) \);
- an orthogonal group \( O^{\mu, \pi}(n, 3) \) for \( \mu \in \{-1, 1\}, \pi \in \{-1, 1\} \), and \( n \geq 4 \);
- one of Fischer’s groups \( Fi_{22}, Fi_{23}, Fi_{24} \).

Then \( G \) contains a nontrivial 2-radical element.

Proof. This immediately follows from the above proposition taking into account the fact that all the listed groups are generated by a class of conjugate 3-transpositions [Fi]. \[ \square \]

9. Sporadic groups

Proposition 9.1. Let \( G \) be a sporadic simple group. Then \( \rho(G) = 3 \) for \( G = Fi_{22}, Fi_{23} \), and \( \rho(G) = 2 \) for all the remaining groups.

More precisely, we shall prove that if \( g \neq 1 \) is a 2-radical element of a sporadic simple group \( G \), then \( G = Fi_{22} \) or \( G = Fi_{23} \) and \( g \) is a 3-transposition. (In the latter cases MAGMA computations show that \( g \) is not a 3-radical element.)
The proof goes case by case. Apart from the theoretical arguments presented below, we used MAGMA for rechecking them (in all the cases except for the Monster). For larger sporadic groups we had to replace most standard MAGMA procedures with our own ones in order to avoid storing the whole group and large subgroups. In particular, to check whether a subgroup under consideration is not solvable, we used the Hall–Thompson criterion [Th]: a group $H$ is nonsolvable if and only if it contains nonidentity elements $a, b, c$ of pairwise coprime orders such that $abc = 1$.

Both in the theoretical proof and in the computer-aided one, we rely on the ATLAS classification of conjugacy classes of maximal cyclic subgroups [Wi].

Let us now prove the proposition. The exposition below is sometimes sketchy; we omit some cases where the proof uses arguments similar to earlier ones.

The main idea is very simple. We first consider the elements of prime orders. It turns out that in most cases one can include a given element $g$ of prime order $p$ of a group $G$ in its proper simple subgroup $H$. If there is a single conjugacy class of cyclic subgroups of order $p$, it is enough to indicate $H$ whose order is divisible by $p$. In the case where there are several conjugacy classes of cyclic subgroups of order $p$, more subtle arguments are needed. We either use ATLAS information on elements $h$ of order $mp$ for some $m$ whose powering gives $g$ and try to include $h$ in some proper simple subgroup $H$, or use some information on subgroup structure of $G$ from the literature. Finally, if $g$ is not contained in any proper simple subgroup of $G$, it happens that its normalizer $N = N_G(g)$ is the unique maximal subgroup of $G$ containing $g$. In that case, one can take $x \in N$ and get $a = [g, x] \in \langle g \rangle$, and take $y$ such that $b = [g, y] \notin N$. Then $\langle a, b \rangle = G$ is not solvable.

If an element $g$ under consideration is of composite order $mp$, we note that it belongs to the centralizer of $h = g^m$ which is of prime order $p$. It remains to use the information from ATLAS on the centralizers of elements of prime orders in sporadic groups. It turns out that in many cases the structure of $C_G(h)$ is as follows: it contains a normal subgroup $Z$ of small exponent such that the quotient $G' = C_G(H)/Z$ is either a smaller simple group or an extension of a simple group by a group of small exponent. Thus if $g$ is a 2-radical element of sufficiently
large exponent, then its image in $G'$ is a nonidentity 2-radical element, and we arrive at a contradiction by induction. In some cases, elements of small exponents require separate consideration.

Below we mostly present theoretical arguments as above for elements of prime orders. We present a more detailed proof for the baby-monster $B$ and a complete proof for the monster $M$.

We follow the subdivision of sporadic groups from ATLAS.

**Mathieu groups:** $M_{11}, M_{12}, M_{22}, M_{23}, M_{24}$.

- $M_{11}$. The elements of orders 2, 3 and 5 are included in $A_5$, and of order 11 — in $PSL_2(11)$.

- $M_{12}$. Any element of order 11 is included in $PSL_2(11)$. All the remaining ones, of types 2A, 2B, 3A, 3B, 5A, are included in $A_5$ (according to [CCNPW, p. 33], $M_{12}$ contains $A_5$'s of types (2A, 3B, 5A) and (2B, 3A, 5A)).

- $M_{22}$. The elements of orders 2, 3, 5 and 7 are included in $A_7$, and of order 11 — in $PSL_2(11)$.

- $M_{23}$. The elements of orders 2, 3, 5 and 11 are included in $M_{11}$, of order 7 — in $A_7$, and the normalizer $N = 23 \cdot 11$ of an element $g$ of order 23 is the unique maximal subgroup of $M_{23}$ containing $g$, so we can apply the argument mentioned above.

- $M_{24}$. Any element of order 23 is included in $PSL_2(23)$, of order 11 — in $M_{23}$, of order 7 — in $PSL_2(7)$, and of order 5 — in $A_5$. According to [CCNPW, p. 96], $M_{24}$ contains $A_5$'s of types (2B, 3A, 5A) and (2B, 3B, 5A), so it remains to consider the class 2A. Fix an element $z$ of type 2B. We have $C_G(z) = E_{26} \cdot S_5$, where $E_{26}$ is an elementary abelian subgroup. Let $g$ be any involution of $A_5 \subset S_5$. Since $g$ centralizes $z$, it cannot be conjugate to $z$, hence $g$ is of type 2A, and we are done.

**Leech lattice groups:** $HS, J_2, Co_1, Co_2, Co_3, McL, Suz$.

Here we shall be a little sketchy describing only the largest Conway group $Co_1$ among the three ones.

$HS$. The elements of orders 3, 7 and 11 are included in $M_{22}$. According to [CCNPW, p. 80], there is an $M_{11} \subset HS$ containing elements of types 2A and 5C, and there is an $A_5$ containing elements of type 2B and 5A. The remaining class 5B also has a representative lying in $A_5$ [GLS, p. 274].
J$_2$. Any element of order 7 can be included in $PSL_3(2)$. According to [CCNPW, p. 42], there are $A_5$’s of types (2B, 3A, 5CD), (2A, 3B, 5AB), thus including the elements of all the other classes.

McL. There are no problems with the elements of orders 2, 7 and 11 — they can all be included, say, in $M_{11}$. By [CCNPW, p. 100], there is a subgroup $PSU_3(5^2)$ containing representatives of 3B, 5A and 5B. It remains to consider the class 3A. Take an element of order 9 in $PSU_4(3^2)$. According to [Wi], its cube belongs to 3A.

Suz. Any element of order 13 belongs to a maximal subgroup $G_2(4)$, and hence to an even smaller subgroup $PSL_2(13)$. The elements of orders 7 and 11 belong to $M_{11}$. On [CCNPW, p. 131] we find an $A_7$ containing representatives of 2B, 3C and 5B, a $PSL_3(3)$ containing representatives of 3B, and a $PSL_2(25)$ containing representatives of 5A and 5B. It thus remains to consider the classes 2A and 3A. To treat 2A, take an element of order 8 in $M_{11}$, then its cube is of type 2A [Wi]. Similarly, the fifth power of an element of order 15 in $J_2$ is of type 3A.

Conway groups: we shall skip the arguments for $Co_2$, $Co_3$.

$Co_1$. The elements of orders 23 and 11 belong to $M_{23}$, and those of order 13 — to $Suz$. The classification of $A_5$’s [Wi83] gives subgroups of types (2B, 3A, 5A), (2B, 3A, 5B), (2B, 3B, 5C), (2B, 3B, 5A), (2B, 3A, 5A). According to [Cu], the classes 7A and 7B have their representatives in $A_7$ and $PSL_3(7)$, and the class 3D, as 3A, belongs to $A_5$. It remains to consider 2A. One can take an element of order 18 in $Co_3$, its 9th power is of type 2A.

Monster sections: He, HN, Th, $Fi_{22}, Fi_{23}, Fi_{24}$, B, M.

Here we shall skip $HN$ (which can be treated using [CCNPW, p. 166] and [NW]) and two larger Fischer groups.

He. The elements of order 17 belong to $PSp_4(4)$, and hence to $PSL_3(16)$. The elements of order 5 lie in $A_5$. We have to consider the classes 2A, 2B, 3A, 3B, 7A, 7C and 7D (7B is a power of 7A and 7E is a power of 7D). First we use the information on (2,3,7)-subgroups from [CCNPW, p. 104]: a subgroup of type (2A, 3B, 7C) is contained in $7 : 3 \times PSL_3(2)$ (and hence 2A belongs to $PSL_3(2)$), and a subgroup of type (2B, 3A, 7AB) is contained in $S_4 \times PSL_3(2)$ (and hence 7A belongs to $PSL_3(2)$ too). Next, we use the information
on the centralizers of involutions [GLS, p. 277]. Since 7D and 3B commute with 2B, they both belong to $PSL_3(2)$. Since 3A commutes with 2A, it belongs to the centralizer of 2A, and hence to $PSL_3(4)$. As to 2A and 2B, the same argument as in the case $M_{24}$ applies, and we conclude that 2A belongs to $PSL_3(2)$ and 2B belongs to $PSL_3(4)$. Finally, since 7C commutes with 3A, it belongs to the centralizer of 3A and hence to $A_7$.

$Th$. The normalizer $N = 31 \cdot 15$ of an element $g$ of order 31 is the unique maximal subgroup of $Th$ containing $g$, so we can proceed as in the case of an element of order 23 in $M_{23}$. Any element of order 19 belongs to $PSL_2(19)$, of order 13 — to $^3D_4(2)$, of orders 2, 5 and 7 — to $A_7$. It remains to treat three classes of elements of order 3. Take an element of order 21 in $PSL_5(2)$, its 7th power is of type $3A$. Taking elements of orders 9 and 15 in $2^{1+8} \cdot A_9$, we obtain $3B$ and $3C$ as their 3rd and 5th power, respectively.

$Fi_{22}$. First recall that this group does contain 2-radical elements, namely, those of the class 2A (3-transpositions), see Section 8 above. Any element of order 13 belongs to $O_7(3)$, and hence to $PSL_3(3)$. The elements of orders 5, 7, 11 lie in $M_{22}$. We have to consider the classes 2B, 2C, 3A, 3B, 3C, 3D. According to [CCNPW, p. 163], there is an $M_{12}$ containing representatives of 2B, 2C, 3C, 3D. We include 3A in $A_{10}$ representing it as the 5th power of an element of order 15 in $A_{10}$. Similarly, we represent 3B as the 6th power of an element of order 18 in $O_8^+(2)$.

$B$. The normalizer $N = 47 \cdot 23$ of an element $g$ of order 47 is the unique maximal subgroup of $B$ containing $g$, so we can proceed as above. The cases of elements of orders 31, 23, 19, 17, 13, 11 and 7 are easy: those of order 31 belong to $PSL_2(31)$, of order 19 — to $Th$, and all the remaining ones can be included, say, in $Fi_{23}$. Furthermore, we use the classification of $A_5$’s [Wi93, Theorems 5.1, 5.2]: in particular, there are subgroups of types $(2B, 3A, 5A)$, $(2D, 3B, 5B)$ and also those containing $2C$. It remains to consider 2A. We get it as the 13th power of an element of order 26 in $Fi_{23}$.

Let now $g$ be an element of composite order $mp$, $m \geq p$. As $p \leq 5$, it suffices to use information on the centralizers of the elements of orders 2, 3 and 5. We have $C_B(2A) = 2 \cdot (2E_6(2)) : 2$, $C_B(2B) = 2^{1+22} \cdot Co_2$, $C_B(2C) = (2^2 \cdot F_4(2)) : 2$, $C_B(2D) = 2^9 \cdot 2^{16} \cdot O_8^+(2) : 2$, $C_B(3A) =$
First suppose \( g \) is of odd order \( mp \), \( m > p \). If \( p = 3 \), then \( g \) centralizes either \( 3A \) or \( 3B \). As the exponent of the extraspecial group \( 3^{1+8} \) equals 3, we get the image of \( g \) of order at least 5 in either \( Fi_{22} \) or \( PSU_4(2) \) whose 2-radical elements can only be of order 2 or 3. Thus \( g \) is not 2-radical. (Note that this argument does not work for the elements of order 9 which will be considered separately.) If \( p = 5 \), we have to consider the elements of orders 35 and 55 which all centralize 5A. Hence each of them induces a nonidentity element of \( HS \), and we are done. The elements of order 25 centralize 5B. As the exponent of the extraspecial group \( 5^{1+4} \) equals 5, each of them induces a nonidentity element of \( A_5 \) which cannot be 2-radical. To finish with the case of odd order, it remains to consider the elements of order 9. According to [Wi], both 9A and 9B can be represented as the 4th power of an element of order 36. Hence any element of order 9 centralizes either \( 2B \) or \( 2D \) and thus belongs to either \( Co_2 \) or \( O_8^+ (2) \), and we are done.

Suppose now \( g \) is of even order \( 2m \) so that \( g \) centralizes an involution of \( B \). If \( m \) is odd, then the image of \( g \) in the simple group involved in the centralizer of the corresponding involution is nonidentity, and we are done. So assume \( m \) to be even, i.e. \( g \) is of order \( 4n \). The elements of order 4 were checked by MAGMA, so suppose \( n > 1 \). According to [Wi], there are no elements of order \( 4n \), \( n > 1 \), powering to \( 2A \). If \( g \) centralizes \( 2B \), then it induces a nonidentity element of \( Co_2 \), and we are done. According to [Wi], the elements of order \( 4n \), \( n > 1 \), powering to \( 2C \) are 12T, 20H and 52A, they were checked separately by MAGMA. Finally, suppose that \( g \) centralizes \( 2D \). If \( n > 2 \), then taking into account that \( C_B(2D) < 2^9 \cdot 2^{16} \cdot PSp_8(2) \), we conclude that \( g \) induces a nonidentity 2-radical element of order greater than 2 in \( PSp_8(2) \) which contradicts to MAGMA computations in that group. Thus it remains to check the elements of order 8 powering to \( 2D \), i.e. 8G, 8J, 8K, 8M and 8N. This was also done by MAGMA.

\( M \). In this case no additional MAGMA computations were needed, we only used the results for smaller groups. Our approach mimics the case of the baby-monster.

The normalizer \( N = 41 \cdot 40 \) of an element \( g \) of order 41 is the unique maximal subgroup of \( M \) containing \( g \), so we can proceed as...
above. Relying on the existing information on maximal subgroups of $M = \text{BrW}$, we include the elements of orders $71, 59, 47, 31, 29, 23, 19, 17, 11$ in $\text{PSL}_2(71), \text{PSL}_2(59), B, B, F_{24}', B, B, B, B$, respectively. Representatives of all the remaining classes appear in [No]: Table 1 on p. 201 gives $13A$ and $13B$ lying in $\text{PSL}_3(3)$, in Section 5 there are exhibited $7A$ and $7B$ lying in $\text{PSL}_3(2)$, and the list of $A_5$'s in Table 3 on p. 202 contains representatives of all classes of elements of orders 2, 3 and 5.

Let now $g$ be an element of composite order $mp$, $m \geq p$. Our arguments are similar to the previous case. As for $B$, we have $p \leq 5$, and it suffices to use information on the centralizers of the elements of orders 2, 3 and 5. We have $C_M(2A) = 2 \cdot B, C_M(2B) = 2^{1+24}, C_{01}, C_M(3A) = 3 \times F_{24}^{'}, C_M(3B) = 3^{1+12}SUZ, C_M(3C) = 3 \times TH, C_M(5A) = 5 \times HN, C_M(5B) = 5^{1+6} : 2J_2$.

First suppose $g$ is of odd order $mp$, $m \geq p$. If $p = 3$, then $g$ centralizes either $3A$, or $3B$, or $3C$. As the exponent of the extraspecial group $3^{1+12}$ equals 3, we get the image of $g$ of order at least 5 in either $F_{22}^{'},$ or $SUZ$, or $TH$ which do not contain 2-radical elements. Thus $g$ is not 2-radical. If $p = 5$, we have to consider the elements of orders 25, 35, 45, 55, 95 and 105. Any of those centralizes either $5A$ or $5B$ and hence induces a nonidentity element of either $HN$ or $J_2$. (We use the fact that the exponent of the extraspecial group $5^{1+6}$ equals 5.)

If $g$ is of even order $2m$, it centralizes either $2A$ or $2B$. If $m > 2$, then $g$ induces a nonidentity element of either $B$ or $Co_1$ which do not contain 2-radical elements. Thus $g$ is not 2-radical and we are done. Let now $g$ be of order 4. Any $4A$-element is the 11th power of $4A$ and hence belongs to $B$. The square of a $4B$-element belongs to $2A$ [Wi]. Therefore $4B$ centralizes $2A$ and thus induces a nonidentity element of $B$. According to [Wi], the 4th power of any element of order 16 belongs to $4C$, hence $4C$ lies, say, in $F_{24}^{'}. Finally, 4D$ is the cube of $12J$ whose 4th power is $3C$. Therefore $12J$ centralizes $3C$ and hence so does $4D$. Thus $4D$ belongs to $TH$, and we are done.

**Pariahs:** $J_1, J_3, J_4, Ru, O'N, Ly.$

$J_1$. The normalizer $N = 19 \cdot 6$ of an element $g$ of order 19 is the unique maximal subgroup of $J_1$ containing $g$, and the above argument applies. If the order of $g$ equals 7, its normalizer $N$ equals $7 \cdot 6$ and is also a maximal subgroup of $J_1$ but is contained in another maximal
subgroup of order 168. However, taking $x \in N$ and $y$ of order 3, we get $a = [g, x] \in \langle g \rangle$ and $b = [g, y]$ of order 15. Since $b$ is outside of both above mentioned maximal subgroups, we have $\langle a, b \rangle = J_1$. The elements of order 11 belong to $PSL_2(11)$, and the elements of orders 2, 3 and 5 belong to $A_5$.

$J_3$. The elements of orders 2 and 5 belong to $A_5$, those of orders 17 and 19 belong to $PSL_2(17)$ and $PSL_2(19)$, respectively. Taking an element of order 9 in $PSL_2(17)$, we obtain $3B$ as its cube, and taking an element of order 15 in $PSL_2(16)$, we obtain $3A$ as its 5th power.

$J_4$. For $p = 43$ or 29, the normalizer of $g$ of order $p$ is the unique maximal subgroup containing $g$, and we apply the above argument. The elements of order 37 lie in $PSU_3(11^2)$, of order 31 — in $PSL_2(32)$, and of orders 3, 5, 7, and 23 — in $M_{24}$. It remains to consider the classes 2A, 2B, 11A, 11B. The centralizers of each of 2A and 2B contain $M_{22}$, and we embed both 2A and 2B in $M_{22}$ using the same argument as in the case $M_{24}$ above. According to [J, Prop. 22 and Prop. 26], we have $11A \subseteq C(2B)$ and $11B \subseteq C(2A)$, so they are both included in $M_{22}$ too.

$Ru$. The elements of orders 29 and 13 lie in the corresponding $PSL$’s, and those of orders 7 and 3 lie in $A_7$. The information on alternating subgroups on [CCNPW, p. 126] gives 2B, 5A and 5B contained there. 2A appears as the square of an element of order 4 in $A_6$.

$O’N$. The elements of order 31 lie in $PSL_2(31)$, of order 19 — in $PSL_3(7)$, and of orders 11, 5, 3 and 2 — in $M_{11}$. As to the classes 7A and 7B, the first appears as the square of an element of order 14 in $PSL_3(7)$, and the second belongs to $PSL_2(7)$ [Wi85, Section 4, p. 471].

$Ly$. For $p = 67$ and 37 we use the same maximal subgroup argument as above. The elements of order 31 belong to $G_2(5)$, and hence to $PSL_3(5)$, and those of orders 11, 7 and 2 — to $A_{11}$. The classification of $A_5$’s [Wi84, Section 6, p. 407] shows that 3B and 5B are included in $A_5$. Both 3A and 5A lie in $G_2(5)$; they can be obtained as the 3th power of an element of order 9 and the 4th power of an element of order 20, respectively.
To finish the proof of the proposition, it remains to check all small groups of Lie type appearing in the above arguments. This was done by straightforward computations.

Proposition 9.1, and hence Theorems 1.15 and 1.4, are proved. □
