EXCEPTIONAL COLLECTIONS OF LINE BUNDLES ON THE BEAUVILLE SURFACE

SERGEY GALKIN, EVGENY SHINDER

Abstract. We construct quasi-phantom admissible subcategories in the derived category of coherent sheaves on the Beauville surface $S$. These quasi-phantoms subcategories appear as right orthogonals to subcategories generated by exceptional collections of maximal possible length 4 on $S$. We prove that there are exactly 6 exceptional collections consisting of line bundles (up to a twist) and these collections are spires of two helices.

Keywords: exceptional collection, quasi-phantom category, Beauville surface

1. Introduction

Bounded derived categories of coherent sheaves on algebraic varieties, their admissible subcategories and semiorthogonal decompositions have been studied intensively by Bondal, Kapranov, Kuznetsov, Orlov, and others [Bon], [BK], [BO], [Kap], [Kuz06], [Kuz09].

It has been questioned which additive invariants of admissible geometric triangulated categories are conservative, that is do not vanish for non-zero categories. Non-vanishing of the Hochschild homology of geometric admissible categories has been conjectured by Kuznetsov in [Kuz09] and non-vanishing of the Grothendieck group has been conjectured by Orlov in early 90’s (unpublished). On the contrary, existence of geometric categories with vanishing Hochschild homology (quasi-phantoms) has been indicated by Katzarkov in [Kat] and existence of geometric categories with vanishing Grothendieck group (phantoms) has been conjectured by Diemer, Katzarkov and Kerr [DKK], both motivated by considerations from mirror symmetry.

Let us consider the simplest interesting case, that of a complex smooth projective surface $S$ of general type. On one hand such a surface is not expected to admit a full exceptional collection in its bounded derived category $D^b(S)$. On the other hand exceptional collections of maximal possible length $\dim H^*(S, \mathbb{Q})$ seem to exist at least in some cases when $p_g(q) = 0$. In such a case the orthogonal complement to the category generated by the exceptional collection has vanishing Hochschild homology [Kuz09], torsion Grothendieck group and generally rather mysterious structure.

The first counterexample to Kuznetsov’s conjecture was given by Böning, Graf von Bothmer and Sosna, who constructed exceptional collections of length 11 on the classical Godeaux surface ($p_g(q) = 0$, $K^2 = 1$, $b_2 = 9$) [BBS]. Alexeev and Orlov [AO] came up with exceptional collections of length 6 on Burniat surfaces ($p_g(q) = 0$, $K^2 = 6$, $b_2 = 4$). Some of the fake projective planes ($p_g(q) = 0$, $K^2 = 9$, $b_2 = 1$) are expected to admit exceptional collections of length 3 [GMS].

In this paper we consider yet another surface with similar properties, the Beauville surface $S$ [Bea]. $S$ is a surface of general type with $p_g(q) = 0$, $K^2 = 8$, $b_2 = 2$, constructed as follows. Let $C$ and $C'$ be two copies of the Fermat quintic

$$X^5 + Y^5 + Z^5 = 0,$$

acted upon by $G = (\mathbb{Z}/5)^2$ in two different ways. We consider the product surface $T = C \times C'$ with the diagonal $G$-action. The latter action turns out to be free for an appropriate choice of $G$-actions on $C$ and $C'$. The Beauville surface $S$ is defined as a quotient $T/G$. According to [BaC], Theorem 3.7 there are two non-isomorphic surfaces that can be obtained this way. We chose one of these two models which we describe in detail in Section 1.

One can find useful the analogy between the Beauville surface $S$ and the quadric surface, that is to think of Beauville surface as a sort of a fake quadric. First of all these two surfaces have the same numerical invariants ($p_g(q) = 0$, $K^2 = 8$, $b_2 = 2$). Furthermore, we prove in Section 2.3 that the Picard group of $S$ is generated modulo
torsion by the bundles \( \mathcal{O}(1,0) \), \( \mathcal{O}(0,1) \) which come as pull-backs from the factors \( C \) and \( C' \). The Riemann-Roch formula on \( S \) implies that
\[
\chi(\mathcal{O}(i,j)) = (i - 1)(j - 1)
\]
also in analogy with the quadric on which we have minus signs replaced by the plus signs. However unlike the quadric case where any line bundle \( \mathcal{O}(-1,k) \) or \( \mathcal{O}(k,-1) \) is acyclic, there are only finitely many isomorphism classes of acyclic line bundles on \( S \).

We list these line bundles in Section 3.2 (Lemma 3.3) and use them to construct six exceptional collections on \( S \) of length 4. We prove that this list exhausts all the exceptional collections consisting of 4 line bundles up to a common twist by a line bundle (Theorem 3.5). We compute dimensions of \( Ext \)-groups between elements of the collections in Proposition 3.7. All of our exceptional collections in question are non-strict. Moreover in all of them both \( Ext^1 \) and \( Ext^2 \) are present unlike the case of the Burniat surfaces where only \( Ext^2 \) appears ([AO], Lemma 4.8). We also note that unlike the case of Burniat surfaces the exceptional collections we present have no blocks, that is no groups of pairwise orthogonal elements.

Confirming the analogy between the Beauville surface and the quadric, it turns out furthermore that line bundles in the exceptional collections on \( S \) are all products of powers of square roots \( K(1,0) \), \( K(0,1) \) of canonical classes coming from the factors \( C \) and \( C' \).

We expect the existence of exceptional collections of line bundles to hold for other product-quotient surfaces with \( p_g = q = 0, K^2 = 8 \) (see e.g. [BaP]) as well. However we do not see at the moment whether there could be a uniform proof for that (see Remark 3.6). We plan to return to this question in the future.

We thank Alexander Kuznetsov for reading a draft of the paper and providing us with many useful comments and remarks. We thank Arend Bayer, Ludmil Katzarkov, Mateusz Michalek, Dmitry Orlov, Yuri Prokhorov, Nicolo Sibilla, Maxim Smirnov for helpful discussions.

2. The Beauville surface and its properties

2.1. Generalities on \( G \)-equivariant line bundles. We list general facts on \( G \)-linearized line bundles and their cohomology (see [Mum] for details).

Let \( G \) be a finite group acting on a smooth projective variety \( X/\mathbb{C} \). The equivariant Picard group \( Pic^G(X) \) is the group of isomorphism classes of \( G \)-linearized line bundles on \( X \). The equivariant Picard group is related to the ordinary Picard group via an exact sequence
\[
(2.1) \quad 0 \to \hat{G} \to Pic^G(X) \to Pic(X)^G,
\]
where \( \hat{G} = Hom(G,\mathbb{C}^*) \) is the group of characters and the first arrow associates to a character \( \chi : G \to \mathbb{C}^* \) a trivial line bundle with the \( G \)-action induced by \( \chi \).

Suppose \( G \) is abelian; then we can describe the equivariant Picard group in terms of \( G \)-invariant divisors on \( X \).

**Lemma 2.1.** Let \( G \) be a finite abelian group. Then the image of \( Pic^G(X) \) in \( Pic(X)^G \) consists of equivalence classes of \( G \)-invariant divisors and (2.1) rewrites as
\[
(2.2) \quad 0 \to \hat{G} \to Pic^G(X) \to \frac{Div(X)^G}{\text{rational equivalence}} \to 0.
\]

**Proof.** We need to prove that for a \( G \)-linearized line bundle \( L \) there exists a section \( s \) with a \( G \)-invariant divisor \( \text{div}(s) \). Let \( W \) be an arbitrary finite-dimensional invariant subspace of meromorphic sections of \( L \).

Since \( G \) is abelian, we may assume \( W \) is one-dimensional, \( W = \mathbb{C} \cdot s \). Now \( s \) is a \( G \)-eigensection, which is equivalent to \( \text{div}(s) \) being \( G \)-invariant.

If \( G \) is a finite group (not necessarily abelian) acting freely on \( X \), then we have an étale covering of smooth projective varieties
\[
\pi : X \to X/G.
\]
In this case specifying a line bundle \( L \) on \( X/G \) is the same as specifying a line bundle \( \bar{L} = \pi^*L \) on \( X \) together with additional structure of \( G \)-linearization. This way we get an identification
\[
\text{Pic}^G(X) = \text{Pic}(X/G).
\]

For any line bundle \( L \) on \( X/G \) the groups \( H^i(X, \pi^*L) \) have a natural structure of \( G \)-representations and we have canonical isomorphisms
\[
H^i(X/G, L) = H^i(X, \pi^*L)^G.
\]

For our computations we need an equivariant version of the Serre duality. For any \( G \)-linearized line bundle on \( X \) we have an isomorphism of \( G \)-representations:
\[
H^k(X, L) \cong (H^{\dim(X) - k}(X, L^* \otimes \omega_X))^*.
\]

**Lemma 2.2.** Let \( V \) be an \( n + 1 \)-dimensional representation of a finite group \( G \). Then we have an isomorphism of \( G \)-linearized line bundles on \( \mathbb{P}(V) \):
\[
\omega_{\mathbb{P}(V)} \cong O(-n - 1)(\det V^*).
\]

**Proof.** The claim follows by taking the determinant of the Euler exact sequence of \( G \)-linearized line bundles on \( \mathbb{P}(V) \):
\[
0 \to \Omega^1_{\mathbb{P}(V)} \to O(-1) \otimes V^* \to O \to 0.
\]

In the notation of Lemma 2.2 let \( F \) be an invariant section of \( O(d) \) on \( \mathbb{P}(V) \) and \( X \) be the hypersurface \( F = 0 \). Then there is a standard adjunction formula giving an isomorphism of \( G \)-linearized line bundles on \( X \):
\[
\omega_X \cong O(d - n - 1)(\det V^*).
\]

**2.2. Equivariant Fermat quintics.** In what follows \( G \) is an abelian group
\[
G = \mathbb{Z}/5^2 = \mathbb{Z}/5 \cdot e_1 \oplus \mathbb{Z}/5 \cdot e_2
\]
acting on a three dimensional vector space \( V \) with induced action on \( \mathbb{P}^2 = \mathbb{P}(V) \) given by
\[
e_1 \cdot (X : Y : Z) = (\zeta_5 X : Y : Z)\]
\[
e_2 \cdot (X : Y : Z) = (X : \zeta_5 Y : Z),
\]
where \( \zeta_5 \) is the 5-th root of unity. Let \( C \) be the plane \( G \)-invariant Fermat quintic curve
\[
X^5 + Y^5 + Z^5 = 0.
\]

We consider the scheme-theoretic quotient \( C/G \) which is isomorphic to \( \mathbb{P}^1 \) and the quotient map
\[
\pi : C \to \mathbb{P}^1
\]
of degree 25. Explicitly we may pick coordinates on \( \mathbb{P}^1 \) such that \( \pi \) is given by the formula
\[
\pi(X : Y : Z) = (X^5 : Y^5).
\]

One easily checks that there are three ramification points on \( \mathbb{P}^1 \) corresponding to the orbits where \( G \) acts non-freely:
\[
\begin{align*}
D_1 &= \{ (0 : -\zeta_5^j : 1), j = 0 \ldots 4 \} \\
D_2 &= \{ (-\zeta_5^j : 0 : 1), j = 0 \ldots 4 \} \\
D_3 &= \{ (\zeta_5^j : -\zeta_5^j : 0), j = 0 \ldots 4 \}
\end{align*}
\]

Stabilizers of the points in \( D_i, i = 1, 2, 3 \) are equal to
\[
\begin{align*}
G_1 &= \mathbb{Z}/5 \cdot e_1 \\
G_2 &= \mathbb{Z}/5 \cdot e_2 \\
G_3 &= \mathbb{Z}/5 \cdot (e_1 + e_2)
\end{align*}
\]
respectively.
Lemma 2.3. The equivariant Picard group $\text{Pic}^G(C)$ splits as a direct sum
$$\text{Pic}^G(C) = \hat{G} \oplus \mathbb{Z} \cdot \mathcal{O}(1).$$

Proof. The claim follows from the exact sequence (2.2). Indeed any $G$-invariant divisor is a combination of $G$-orbits on $C$. Any orbit is either a smooth fiber of $\pi$ consisting of 25 points or one of the divisors (2.5) consisting of 5 points. Since $D_1, D_2, D_3$ are hyperplane sections of $C$ they give rise to the same element $\mathcal{O}(1)$ in the Picard group $\text{Pic}(C)$. All the generic fibers are of $\pi$ are linearly equivalent to each other, and also equivalent to $\mathcal{O}(5)$.

Therefore the third term in the exact sequence (2.2) is $\mathbb{Z} \cdot \mathcal{O}(1)$ and (2.2) splits giving the required decomposition. □

We introduce some notation which will help us to keep track of appearing characters in the cohomology representations. To any $\mathbb{Z}_+$-graded $G$-representation $W$ we attach a polynomial

$$[W] \in K_0(\mathbb{Z}_+ - \text{graded} \; (\mathbb{Z}/5)^2 - \text{representations}) = \mathbb{Z}[q,x,y]/(x^5 - 1, y^5 - 1).$$

By definition we have the following properties of the polynomial $[W]$:

$$[W \oplus W'] = [W] + [W'],$$
$$[W \otimes W'] = [W] \cdot [W'],$$
$$[W^\ast] = [W]_{x=q^y, y=q^x}.$$}

Later we will use the same bracket notation $[i,j]$, $i,j \in \mathbb{Z}/5$ for the character $e_1 \mapsto \zeta_5^i, e_2 \mapsto \zeta_5^j$ which will hopefully not lead to a confusion. For example we have

$$[W[i,j]] = [W] \cdot x^iy^j.$$

We now proceed to computing cohomology groups of line bundles $\mathcal{O}(n), n \leq 5$ on $C$ taking into account the $G$-action. For $n \leq 4$ we have

$$H^0(C, \mathcal{O}(n)) \cong H^0(\mathbb{P}^2, \mathcal{O}(n)) = \bigoplus_{i,j \geq 0, i+j \leq n} \mathbb{C} \cdot X^i Y^j Z^{n-i-j}.$$  

For $n = 5$ we quotient out the representation space $H^0(\mathbb{P}^2, \mathcal{O}(5))$ by the relation $X^5 + Y^5 + Z^5 = 0$. Thus we have

$$[H^0(C, \mathcal{O}(n))] = \sum_{0 \leq i,j \leq 4, i+j \leq 5} x^i y^j, \quad 0 \leq n \leq 4$$

(2.8)

(2.9)
We introduce the curve $C'$ which is defined by the same equation
\[ X^5 + Y^5 + Z^5 = 0 \]
as $C$ but has a different $G$-action. We pick the $G$-action on $C'$ to be defined as
\[ e_1 \cdot (X : Y : Z) = (\zeta_5^2 X : \zeta_5^3 Y : Z) \]
\[ e_2 \cdot (X : Y : Z) = (\zeta_5 X : \zeta_5^3 Y : Z) \]
For this action points in divisors $D_i$, $i = 1, 2, 3$ defined as in (2.5) have stabilizers
\[ G'_1 = \mathbb{Z}/5 \cdot (e_1 + 2e_2) \]
\[ G'_2 = \mathbb{Z}/5 \cdot (e_1 + 3e_2) \]
\[ G'_3 = \mathbb{Z}/5 \cdot (e_1 + 4e_2) \]
respectively.

It follows from the construction that for any $n \in \mathbb{Z}$ we have a formula
\[ [H^* (C', \mathcal{O}(n))][q, x, y] = [H^* (C, \mathcal{O}(n))][q, x^2y, y^4] \]
and that the canonical class on $C'$ is equal to $\mathcal{O}(2)[1, 4]$.

We introduce the notation
\[ K_C(1) = \mathcal{O}(1)[3, 3] \]
\[ K_{C'}(1) = \mathcal{O}_{C'}(1)[3, 2] \]
for the unique square roots of the canonical classes on $C$ and $C'$ respectively.

2.3. Line bundles and cohomological invariants of the Beauville surface. We let $T = C \times C'$ with the diagonal $G$-action. Since the stabilizers in (2.6) and (2.10) are distinct, the $G$-action on $T$ is free. One can check that the corresponding smooth quotient Beauville surface $S = T/G$ is of general type with $p_g = q = 0, K^2 = 8$ (Chapter X, Exercise 4 in [Bea]). The Noether formula gives $b_2 = 2$. Since $p_g = q = 0$, the exponential exact sequence gives an identification
\[ \text{Pic}(S) = H^2(S, \mathbb{Z}). \]
Modulo torsion $\text{Pic}(S)$ is an indefinite unimodular lattice of rank 2, that is a hyperbolic plane.

We introduce $G$-linearized line bundles $\mathcal{O}(i, j)$ and $\mathcal{K}(i, j)$ for $i, j \in \mathbb{Z}$ as follows:
\[ \mathcal{O}(i, j) = p_1^*(\mathcal{O}(i)) \otimes p_2^*(\mathcal{O}(j)) \]
\[ \mathcal{K}(i, j) = p_1^*(\mathcal{K}(i)) \otimes p_2^*(\mathcal{K}(j)) = \mathcal{O}(i, j)[3i + 3j, 3i + 2j]. \]

We will often prefer to work with the lattice $\mathcal{K}(i, j)$ since the exceptional collections we write down in Section 3 are all contained in this lattice.

We note however that $\mathcal{K}(i, j)$ and $\mathcal{O}(i, j)$ differ by a torsion line bundle hence are equivalent from the point of view of intersection pairing. In particular in the following Proposition $\mathcal{O}(i, j)$ can be replaced by $\mathcal{K}(i, j)$ (with an obvious exception of the second claim).

**Proposition 2.4.** 1. The Picard group of $S$ splits as
\[ \text{Pic}(S) = \text{Pic}^G(T) = \hat{G} \cdot [\mathcal{O}] \oplus \mathbb{Z} \cdot [\mathcal{O}(1, 0)] \oplus \mathbb{Z} \cdot [\mathcal{O}(0, 1)]. \]
2. The canonical class $\omega_S$ is equal to $K(2, 2) = \mathcal{O}(2, 2)[2, 0]$.
3. The intersection pairing is given by
\[ \langle \mathcal{O}(i_1, j_1)(\chi_1) \cdot \mathcal{O}(i_2, j_2)(\chi_2) \rangle = i_1j_2 + j_1i_2. \]
4. The Euler characteristic of a line bundle $L = \mathcal{O}(i, j)(\chi)$ is equal to $(i - 1)(j - 1)$.

**Proof.** Let us first prove that
\[ (\mathcal{O}(1, 0) \cdot \mathcal{O}(0, 1)) = 1. \]
For that we pull-back the intersection to $T$:
\[ 25 \cdot (\mathcal{O}(1, 0) \cdot \mathcal{O}(0, 1)) = (\pi^*\mathcal{O}(1, 0) \cdot \pi^*\mathcal{O}(0, 1))_T = (5[pT \times C'] \cdot 5[C \times pT])_T = 25, \]
which implies (2.12). Since we also obviously have
\[(\mathcal{O}(1,0)^2) = (\mathcal{O}(0,1)^2) = 0,\]
it follows that \(\mathcal{O}(1,0)\) and \(\mathcal{O}(0,1)\) span a hyperbolic plane and therefore generate the whole Picard group modulo torsion.

To prove the first claim we use the fact that \(H_1(S) = (\mathbb{Z}/5)^2\) [BaC], Theorem 4.3, (4), which implies that
\[
\text{Pic}(S)_{\text{tors}} = H^2(S, \mathbb{Z})_{\text{tors}} = H_1(S, \mathbb{Z})_{\text{tors}} = (\mathbb{Z}/5)^2.
\]
Since by (2.2) \(\hat{G} \cong (\mathbb{Z}/5)^2\) is contained in \(\text{Pic}(S)\), \(\text{Pic}(S)_{\text{tors}} \cong \hat{G}\) and we get a decomposition
\[
\text{Pic}(S) = \hat{G} \cdot [\mathcal{O}] \oplus \text{Pic}(S)/\text{tors} = \hat{G} \cdot [\mathcal{O}] \oplus \mathbb{Z} \cdot [\mathcal{O}(1,0)] \oplus \mathbb{Z} \cdot [\mathcal{O}(0,1)].
\]
The second claim follows from
\[
\omega_S = p_1^* \omega_C \oplus p_2^* \omega_{C^\vee} = \mathcal{K}(2,0) \otimes \mathcal{K}(0,2) = \mathcal{O}(2,0)[1,1] \otimes \mathcal{O}(0,2)[1,4].
\]
The third claim of the Lemma follows from (2.12),(2.13), and the fact that twisting by torsion classes does not affect the intersection form.

To check the fourth claim we use Riemann-Roch formula:
\[
\chi(L) = 1 + \frac{(L \cdot L \otimes \omega_S^2)}{2} = 1 + \frac{(\mathcal{O}(i,j) \cdot \mathcal{O}(i-2,j-2)(\chi - [2,0]))}{2} = 1 + \frac{(i(j-2) + j(i-2))}{2} = (i-1)(j-1).
\]

We have a Künneth-type formula for isomorphism classes of graded representations (recall the notation from (2.7):
\[(2.14) \quad [H^*(T, \mathcal{K}(i,j))](q, x, y) = [H^*(C, \mathcal{K}(i))](q, x, y) \cdot [H^*(C', \mathcal{K}(j))](q, x, y),\]
and the analogous formula with \(\mathcal{K}(i,j)\) replaced by \(\mathcal{O}(i,j)\). This is simply a reformulation of the Künneth formula
\[
H^*(C \times C', p_1^* L_1 \otimes p_2^* L_2) = H^*(C, L_1) \otimes H^*(C', L_2).
\]
with the \(G\)-action on both sides taken into account.

In the following Lemma we perform necessary computations which will be used later for computing Hochschild homology of \(S\) as well as cohomology of \(dg\)-algebras of the exceptional collections on \(S\).

Lemma 2.5. Some cohomology ranks \(h^0(\mathcal{K}(i,j)) + q h^1(\mathcal{K}(i,j)) + q^2 h^2(\mathcal{K}(i,j))\) are given in the table:

<table>
<thead>
<tr>
<th>(i)</th>
<th>(-3)</th>

</tbody>
</table>

Proof. The entries of the table are in agreement with the Serre isomorphism
\[
h^*(S, \mathcal{K}(i,j)) = h^{2-n}(S, \mathcal{K}(2-i, 2-j)),
\]
therefore it is sufficient to consider \(i, j\) from the table with \(i, j \geq 1\). The Euler characteristic of \(\mathcal{K}(i,j)\) is equal to \((i-1)(j-1)\). By Kodaira vanishing theorem there is no higher cohomology for \(i, j \geq 3\). The rest is done using the
K"unneth formula (2.14) and (2.8), (2.9), (2.11) which we use to compute:

\[ H^*(C, \mathcal{K}(1)) = x^4y^3 + x^3y^4 + x^2y^5 + x^4y^2 + qxy^2 \]
\[ H^*(C', \mathcal{K}(1)) = x^3y^3 + x^2 + x^3y + qy^2 + x^2y^2 \]
\[ H^*(C, \mathcal{K}(2)) = x^3y + x^2y^2 + xy^3 + x^2y + xy^2 + xy + q \]
\[ H^*(C', \mathcal{K}(2)) = x^2y^3 + xy^4 + x^4 + x^3 + y^2 + y + q \]
\[ H^*(C, \mathcal{K}(3)) = x^4y^3 + x^3y^4 + x^2y^5 + x^4y + xy^4 + x^4 + y^4 + x + y + 1 \]
\[ H^*(C', \mathcal{K}(3)) = x^4y^3 + x^3y^4 + x^2y^5 + x^4y + xy^4 + x^2y + xy^2 + x + 1 \]
\[ H^*(C, \mathcal{K}(4)) = x^4y^4 + x^4y^3 + x^2y^6 + x^3y^4 + x^2y^5 + x^2 + x^2y^2 + x + y^2 \]
\[ H^*(C', \mathcal{K}(4)) = x^4y^4 + x^4y^2 + x^2y^4 + x^3y^2 + x^2y^3 + x^3y + xy^3 + y^4 + x^3 + y^3 + x^2 + xy + y^2 + x. \]

(2.15)

**Lemma 2.6.** The Hochschild cohomology groups \( HH^*(S, \mathbb{C}) = \bigoplus_{p+q=n} H^p(S, \Lambda^q T_S) \) of \( S \) are given below.

\[
HH^0(S) = \mathbb{C} \\
HH^1(S) = 0 \\
HH^2(S) = 0 \\
HH^3(S) = H^2(S, T_S) = \mathbb{C}^6 \\
HH^4(S) = H^2(S, \Lambda^2 T_S) = \mathbb{C}^6.
\]

**Proof.** We have

\[
H^p(S, \Lambda^q T_S) = H^p(T, \Lambda^q T_T)\]

and

\[
T_T = p_1^* T_C \oplus p_2^* T_C' = \mathcal{K}(-2, 0) \oplus \mathcal{K}(0, -2) \\
\Lambda^2 T_T = p_1^* T_C \oplus p_2^* T_C' = \mathcal{K}(-2, -2).
\]

Now the cohomology groups in question are found in the table of Lemma 2.5.

**Lemma 2.7.** The Grothendieck group of the Beauville surface \( S \) has a decomposition

\[
K_0(S) = \mathbb{Z}^3 \oplus (\mathbb{Z}/5)^2.
\]

**Proof.** By the results of Kimura [Kim], Bloch conjecture is known for all surfaces with \( p_g = 0 \) covered by products of curves, hence \( CH_0(S) = \mathbb{Z}. \) Consider the topological filtration \( F^i \subset K_0(S) \) given by the codimension of support [Ful]. By Riemann-Roch theorem without denominators [Ful] we have

\[
F^0/F^1 \cong \mathbb{Z} \\
F^1/F^2 \cong Pic(S) \cong \mathbb{Z}^2 \oplus (\mathbb{Z}/5)^2 \\
F^2 \cong CH_0(S) \cong \mathbb{Z}.
\]

Extension \( 0 \to F^1 \to F^0 \to \mathbb{Z} \to 0 \) always splits for group-theoretic reasons, so

\[
K_0(S) = \mathbb{Z} \oplus F^1.
\]

We have a short exact sequence

(2.16)

\[
0 \to \mathbb{Z} \to F^1 \to Pic(S) \to 0.
\]

We have to prove that (2.16) splits, that is there exists a retraction \( F^1 \to \mathbb{Z}. \) In general such a retraction exists whenever the image of \( i(1) \) in \( F^1/tors \) is not divisible by any integer \( a > 1. \) Recall that \( i(1) = [\mathcal{O}_P] \in F^1 \subset K_0(T) \) where \( P \) is a point of \( S. \) Assume that \( [\mathcal{O}_P] = a \cdot A + \alpha, \) where \( \alpha \) is a torsion element. Then

\[
1 = \chi(\mathcal{O}, \mathcal{O}_P) = \chi(\mathcal{O}, aA + \alpha) = a \chi(\mathcal{O}, A)
\]
since $a$ is positive integer and $\chi(O,A)$ is integer last equality implies $a = 1$. 

3. Exceptional collections on the Beauville surface

3.1. Numerically exceptional collections and helices. We call a sequence of line bundles

$$L_1, \ldots, L_n$$

on a variety numerically exceptional if for all $j > i$

$$\chi(L_j, L_i) = \sum_l (-1)^l \dim \text{Ext}^l(L_j, L_i) = 0.$$

Any exceptional collection is obviously numerically exceptional as well. We note that in order to speak about numerically exceptional collections we only need to consider classes of $L_i$’s modulo torsion. This implies that a sequence $L_1, \ldots, L_n$ forms a numerically exceptional collection on $S$ if and only if any twist $L_1(\chi_1), \ldots, L_n(\chi_n)$ does. In particular we will not make a distinction between $\mathcal{O}(i,j)$ and $K(i,j)$ when investigating numerically exceptional collections.

Lemma 3.1. A sequence

$$\mathcal{O}, L_1, L_2, L_3$$

of line bundles on $S$ is numerically exceptional if and only if it belongs to one of the following four numerical types:

$(\text{I}c)$ $\mathcal{O}, \mathcal{O}(-1,0), \mathcal{O}(c-1,-1), \mathcal{O}(c-2,-1), c \in \mathbb{Z}$

$(\text{II}c)$ $\mathcal{O}, \mathcal{O}(0,-1), \mathcal{O}(-1,c-1), \mathcal{O}(-1,c-2), c \in \mathbb{Z}$

$(\text{III}c)$ $\mathcal{O}, \mathcal{O}(-1,c), \mathcal{O}(-1,c-1), \mathcal{O}(-2,-1), c \in \mathbb{Z}$

$(\text{IV}c)$ $\mathcal{O}, \mathcal{O}(c,-1), \mathcal{O}(c-1,-1), \mathcal{O}(-1,-2), c \in \mathbb{Z}$

We note that $I_0 = III_0, II_0 = IV_0$ and also that types $I_c$ and $II_c$ are characterized by the property $L_3 \cong L_1 \otimes L_2$.

Proof. By Proposition 2.4(4) the sequence

$$\mathcal{O}, \mathcal{O}(a_1,b_1), \mathcal{O}(a_2,b_2), \mathcal{O}(a_3,b_3)$$

is numerically exceptional if and only if all of the vectors $(a_i, b_i), (a_j - a_i, b_j - b_i), j > i$ have one of the coordinates equal to -1. The rest of the proof is left to the reader.

If we consider a general sequence of line bundles

$$L_0, L_1, L_2, L_3$$

on $S$, then it is (numerically) exceptional if and only if

$$\mathcal{O}, L_1 \otimes L_0^*, L_2 \otimes L_0^*, L_3 \otimes L_0^*$$

is (numerically) exceptional. We say that the sequence (3.1) is of type $I_c, II_c, III_c$ or $IV_c$ if (3.2) is of this type.

In order to study exceptional collections on $S$ more efficiently we will use so-called helices ([GR], [Bon], [BP]). We call a sequence $E_\bullet = (E_i, i \in \mathbb{Z})$ of sheaves on a smooth variety $X$ a helix of period $n$ if

$$E_{i-kn} = E_i \otimes \omega_X^{\otimes k}$$

for all $0 \leq i \leq n - 1$, $k \in \mathbb{Z}$. 1 Given a sequence $E_0, \ldots, E_{n-1}$ of sheaves on $X$ we can extend it to a helix by the formula above.

Any subsequence of a helix consisting of $n$ consecutive elements $E_a, E_{a+1}, \ldots, E_{a+n-1}$ will be called a spire. By Serre duality an arbitrary spire of a helix is a (numerically) exceptional collection if and only if $E_0, \ldots, E_{n-1}$ is a (numerically) exceptional collection. We will sometimes represent a helix $E_\bullet$ as a sequence of $n + 1$ consecutive spires

$$E_a \rightarrow E_{a+1} \rightarrow \cdots \rightarrow E_{a+n},$$

for some $a \in \mathbb{Z}$ where $E_j = \{E_j, E_{j+1}, \ldots, E_{j+n-1}\}$. Note that since $n$ is the period of $E_\bullet$, $E_{a+n}$ differs from $E_a$ by a twist by $\omega_X$.

---

1The definition of helix we use coincides with that from [Bon] up to shifts which we have dropped for convenience. The definition of helix in [BP] which is given in terms of mutations rather than the Serre functor differs from ours since the collections we consider are not full.
We now may ask what are the helices formed by numerically exceptional collections of Lemma 3.1. The proof of the following Lemma is straightforward from definitions.

**Lemma 3.2.** Numerically exceptional helices on \( S \) formed by line bundles belong to one of the two families:
\[
I_c \rightarrow IV_c \rightarrow I_{-c} \rightarrow IV_{-c} \rightarrow I_c, \ c \in \mathbb{Z}
\]
\[
II_c \rightarrow III_c \rightarrow II_{-c} \rightarrow III_{-c} \rightarrow II_c, \ c \in \mathbb{Z}.
\]

3.2. **Acyclic line bundles and exceptional collections.** We will now investigate which of the numerically exceptional collections of Lemma 3.1 can be lifted to exceptional collections. Here by a lift we mean a lift with respect to the morphism
\[
\mathbb{Z}^2 \oplus \hat{\mathcal{G}} = \text{Pic}(S) \rightarrow \text{Pic}(S)/\text{tors} = \mathbb{Z}^2,
\]
that is a choice of a character \( \chi \in \hat{\mathcal{G}} \). We will need a detailed study of the characters that may appear in the cohomology groups of sheaves on \( T \).

For a \( G \)-linearized line bundle on \( T \) we define the acyclic set of \( L \) as
\[
\mathcal{A}(L) := \{ \chi \in \text{Hom}(G, \mathbb{C}^*) : \chi \notin [H^*(T, L)] \}
\]
By definition \( L(\chi) \) is acyclic if and only if \(-\chi \in \mathcal{A}(L)\). Since by Proposition 2.4(1), any line bundle on \( S \) is isomorphic to some \( \mathcal{K}(i, j)(\chi) \), we see from the next lemma that there are 39 isomorphism classes of acyclic line bundles on \( S \).

**Lemma 3.3.** The only nonempty acyclic sets of line bundles \( \mathcal{K}(i, j) \) on \( S \) are:
\[
\mathcal{A}(\mathcal{K}(1, -2)) = \{ [0, 0] \}
\]
\[
\mathcal{A}(\mathcal{K}(1, -1)) = \{ [0, 3], [2, 0], [3, 2] \}
\]
\[
\mathcal{A}(\mathcal{K}(1, 0)) = \{ [0, 0], [0, 1], [0, 2], [1, 4], [2, 3], [3, 0], [4, 0] \}
\]
\[
\mathcal{A}(\mathcal{K}(1, 1)) = \{ [0, 0], [1, 2], [2, 1], [2, 2], [3, 3], [3, 4], [4, 3] \}
\]
\[
\mathcal{A}(\mathcal{K}(1, 2)) = \{ [0, 0], [0, 3], [0, 4], [1, 0], [2, 0], [3, 2], [4, 1] \}
\]
\[
\mathcal{A}(\mathcal{K}(1, 3)) = \{ [0, 2], [2, 3], [3, 0] \}
\]
\[
\mathcal{A}(\mathcal{K}(1, 4)) = \{ [0, 0] \}
\]
\[
\mathcal{A}(\mathcal{K}(-1, 1)) = \{ [0, 0] \}
\]
\[
\mathcal{A}(\mathcal{K}(0, 1)) = \{ [0, 0], [3, 3], [3, 4], [4, 3] \}
\]
\[
\mathcal{A}(\mathcal{K}(2, 1)) = \{ [0, 0], [1, 2], [2, 1], [2, 2] \}
\]
\[
\mathcal{A}(\mathcal{K}(3, 1)) = \{ [0, 0] \}.
\]

**Proof.** Since by Proposition 2.4(4) any bundle \( \mathcal{K}(i, j)(\chi) \) with \( i \neq 1 \) and \( j \neq 1 \) is not acyclic we restrict to the cases \( i = 1 \) or \( j = 1 \). We note in addition that our claim is consistent with the Serre duality: \( \mathcal{A}(\mathcal{K}(i, j)) \) is in duality with \( \mathcal{A}(\mathcal{K}(2 - i, 2 - j)) \); therefore we only need to consider the cases \( \mathcal{K}(1, j), \mathcal{K}(i, 1), i, j \geq 1 \).

For \( i, j \geq 3 \) we have an implication
\[
\mathcal{A}(\mathcal{K}(i, j)) = \emptyset \implies \mathcal{A}(\mathcal{K}(i + 1, j)) = \emptyset, \mathcal{A}(\mathcal{K}(i, j + 1)) = \emptyset,
\]
therefore it is sufficient to prove that
\[
\mathcal{A}(\mathcal{K}(1, 5)) = \emptyset
\]
\[
\mathcal{A}(\mathcal{K}(4, 1)) = \emptyset
\]
and to compute \( \mathcal{A}(L) \) for line bundles
\[
\mathcal{K}(1, 1), \mathcal{K}(1, 2), \mathcal{K}(1, 3), \mathcal{K}(1, 4), \mathcal{K}(2, 1), \mathcal{K}(3, 1).
\]
This is done by looking at the terms of the products of the polynomials in (2.15).

**Lemma 3.4.** Let \( L_1, L_2, L_3 \) be line bundles on \( S \). A sequence
\[
\mathcal{O}, L_1(\chi_1), L_2(\chi_2), L_3(\chi_3)
\]
forms an exceptional collection if and only if the following conditions hold:
\[ \chi_1 \in \mathcal{A}(L_1^*) \]
\[ \chi_2 \in \mathcal{A}(L_2^*) \]
\[ \chi_3 \in \mathcal{A}(L_3^*) \]
\[ \chi_2 - \chi_1 \in \mathcal{A}(L_1 \otimes L_2^*) \]
\[ \chi_3 - \chi_1 \in \mathcal{A}(L_1 \otimes L_3^*) \]
\[ \chi_3 - \chi_2 \in \mathcal{A}(L_2 \otimes L_3^*) \].

Proof. The statement is a reformulation of the definition of exceptional collection. \( \square \)

Theorem 3.5. The following list contains all exceptional collections of length 4 consisting of line bundles on \( S \) (up to a common twist by a line bundle):

\[ (I_1) \mathcal{O}, \mathcal{K}(-1,0), \mathcal{K}(0,-1), \mathcal{K}(-1,-1) \]
\[ (IV_1) \mathcal{O}, \mathcal{K}(1,-1), \mathcal{K}(0,-1), \mathcal{K}(-1,-2) \]
\[ (I_{-1}) \mathcal{O}, \mathcal{K}(-1,0), \mathcal{K}(-2,-1), \mathcal{K}(-3,-1) \]
\[ (IV_{-1}) \mathcal{O}, \mathcal{K}(-1,-1), \mathcal{K}(-2,-1), \mathcal{K}(-1,-2) \]
\[ (II_0 = IV_0) \mathcal{O}, \mathcal{K}(0,-1), \mathcal{K}(-1,-1), \mathcal{K}(-1,-2) \]
\[ (I_0) \mathcal{O}, \mathcal{K}(-1,0), \mathcal{K}(-1,-1), \mathcal{K}(-2,-1). \]

These six collections are spires of the two helices

\[ (H_1) I_1 \rightarrow IV_1 \rightarrow I_{-1} \rightarrow IV_{-1} \rightarrow I_1 \]
\[ (H_2) I_0 \rightarrow II_0 \rightarrow I_0. \]

Proof. Because of Remark 3.2 we only need to consider numerically exceptional collections of types \( I_c, c \geq 0, II_c, c > 0 \) and all helices formed by them. Let us start by listing all numerically exceptional collections

\[ \mathcal{O}, L_1, L_2, L_3 = L_1 \otimes L_2 \]

of line bundles of the types as above satisfying the properties:

\[ \mathcal{A}(L_1^*) \neq \emptyset; \mathcal{A}(L_2^*) \neq \emptyset; \mathcal{A}(L_3^*) \neq \emptyset \]
\[ \mathcal{A}(L_1 \otimes L_2^*) \neq \emptyset. \]

By Lemma 3.3 these properties are necessary for \( \mathcal{O}, L_1, L_2, L_3 \) to form an exceptional collection. With the help of Lemmas 3.1 and 3.3 we get the following list:

\[ I_0, I_1, II_1, II_2. \]

Finally we check whether there are characters \( \chi_1, \chi_2, \chi_3 \) for each of these types of collections that will satisfy the conditions of Lemma 3.4.

**Type** \( I_0 \): \( \mathcal{O}, \mathcal{K}(-1,0)(\chi_1), \mathcal{K}(-1, -1)(\chi_2), \mathcal{K}(-2, -1)(\chi_3) \) with conditions

\[ \chi_1 - \chi_2 \in \mathcal{A}(\mathcal{K}(1,0)) = \{ [0,0], [0,1], [0,2], [1,4], [2,3], [3,0], [4,0]\} \]
\[ \chi_2 - \chi_1 \in \mathcal{A}(\mathcal{K}(1,1)) = \{ [0,0], [1,2], [2,1], [2,2], [3,3], [3,4], [4,3]\} \]
\[ \chi_3 \in \mathcal{A}(\mathcal{K}(2,1)) = \{ [0,0], [1,2], [2,1], [2,2]\} \]
\[ \chi_2 - \chi_1 \in \mathcal{A}(\mathcal{K}(0,1)) = \{ [0,0], [3,3], [3,4], [4,3]\} \]

For each choice of \( \chi_3 \) we find possible \( \chi_1, \chi_2 \) from conditions

\[ \chi_1 \in \mathcal{A}(\mathcal{K}(1,0)) \cap \chi_3 - \mathcal{A}(\mathcal{K}(1,1)) \]
\[ \chi_2 \in \mathcal{A}(\mathcal{K}(1,1)) \cap \chi_3 - \mathcal{A}(\mathcal{K}(1,0)) \]

and look for those \( \chi_1, \chi_2 \) that satisfy

\[ \chi_2 - \chi_1 \in \mathcal{A}(\mathcal{K}(0,1)). \]

1. \( \chi_3 = [0,0] \). Using (3.6) we find the only set of characters

\[ \chi_1 = \chi_2 = [0,0] \]
and it obviously satisfies the condition (3.7) as well. Thus we obtain the collection
\((I_0) \mathcal{O}, \mathcal{K}(-1,0), \mathcal{K}(-1,-1), \mathcal{K}(-2,-1)\)
and the one in the same helix
\((II_0 = IV_0) \mathcal{O}, \mathcal{K}(0,-1), \mathcal{K}(-1,-1), \mathcal{K}(-1,-2)\).

2. \(\chi_3 = [1, 2]\). (3.6) reads as:
\[
\begin{align*}
\chi_1 & \in \{[0, 0], [4, 0]\} \\
\chi_2 & \in \{[1, 2], [2, 2]\}
\end{align*}
\]
and none of these pairs satisfies (3.7).

3. \(\chi_3 = [2, 1]\). (3.6) reads as:
\[
\begin{align*}
\chi_1 & \in \{[0, 0], [1, 4]\} \\
\chi_2 & \in \{[1, 2], [2, 1]\}
\end{align*}
\]
and none of these pairs satisfies (3.7).

4. \(\chi_3 = [2, 2]\) (3.6) reads as:
\[
\begin{align*}
\chi_1 & \in \{[0, 1], [0, 0]\} \\
\chi_2 & \in \{[2, 1], [2, 2]\}
\end{align*}
\]
and none of these pairs satisfies (3.7).

**Type I:** \(\mathcal{O}, \mathcal{K}(-1,0)(\chi_1), \mathcal{K}(0,-1)(\chi_2), \mathcal{K}(-1,-1)(\chi_3)\) with conditions
\[
\begin{align*}
\chi_1 - \chi_2 & \in \mathcal{A}(\mathcal{K}(1,0)) = \{[0, 0], [0, 1], [0, 2], [1, 4], [2, 3], [3, 0], [4, 0]\} \\
\chi_2 - \chi_1 & \in \mathcal{A}(\mathcal{K}(0,1)) = \{[0, 0], [3, 3], [3, 4], [4, 3]\} \\
\chi_3 & \in \mathcal{A}(\mathcal{K}(1,1)) = \{[0, 0], [1, 2], [2, 1], [2, 2], [3, 3], [3, 4], [4, 3]\} \\
\chi_2 - \chi_1 & \in \mathcal{A}(\mathcal{K}(-1,1)) = \{[0, 0]\}
\end{align*}
\]
From the conditions on \(\chi_1, \chi_2\) we find that \(\chi_1 = \chi_2 = [0, 0]\). Then
\[
\chi_3 \in \mathcal{A}(\mathcal{K}(1,1)) \cap \mathcal{A}(\mathcal{K}(1,0)) \cap \mathcal{A}(\mathcal{K}(0,1)) = \{[0, 0]\}.
\]
This way we get exceptional collection
\((I_1) \mathcal{O}, \mathcal{K}(-1,0), \mathcal{K}(0,-1), \mathcal{K}(-1,-1)\)
and three others lying in the same helix
\((IV_1) \mathcal{O}, \mathcal{K}(1,-1), \mathcal{K}(0,-1), \mathcal{K}(-1,-2)\)
\((I_{-1}) \mathcal{O}, \mathcal{K}(-1,0), \mathcal{K}(-2,-1), \mathcal{K}(-3,-1)\)
\((IV_{-1}) \mathcal{O}, \mathcal{K}(-1,-1), \mathcal{K}(-2,-1), \mathcal{K}(-1,-2)\).

**Type II:** \(\mathcal{O}, \mathcal{K}(0,-1)(\chi_1), \mathcal{K}(-1,0)(\chi_2), \mathcal{K}(-1,-1)(\chi_3)\) with conditions
\[
\begin{align*}
\chi_1 - \chi_2 & \in \mathcal{A}(\mathcal{K}(0,1)) = \{[0, 0], [3, 3], [3, 4], [4, 3]\} \\
\chi_2 - \chi_1 & \in \mathcal{A}(\mathcal{K}(1,0)) = \{[0, 0], [0, 1], [0, 2], [1, 4], [2, 3], [3, 0], [4, 0]\} \\
\chi_3 & \in \mathcal{A}(\mathcal{K}(1,1)) = \{[0, 0], [1, 2], [2, 1], [2, 2], [3, 3], [3, 4], [4, 3]\} \\
\chi_2 - \chi_1 & \in \mathcal{A}(\mathcal{K}(-1,1)) = \{[0, 0], [2, 0], [3, 2]\}
\end{align*}
\]
There exist no \(\chi_1, \chi_2\) satisfying the respective conditions.

**Type II:** \(\mathcal{O}, \mathcal{O}(0,-1)(\chi_1), \mathcal{O}(-1,0)(\chi_2), \mathcal{O}(-1,0)(\chi_3)\) with conditions
\[
\begin{align*}
\chi_1 - \chi_2 & \in \mathcal{A}(\mathcal{K}(0,1)) = \{[0, 0], [3, 3], [3, 4], [4, 3]\} \\
\chi_2 - \chi_1 & \in \mathcal{A}(\mathcal{K}(1,0)) = \{[0, 0], [3, 0], [4, 0]\} \\
\chi_3 & \in \mathcal{A}(\mathcal{K}(1,1)) = \{[0, 0], [0, 0], [0, 0], [0, 0], [0, 0], [0, 0], [0, 0]\} \\
\chi_2 - \chi_1 & \in \mathcal{A}(\mathcal{K}(-1,0)) = \{[0, 0]\}
\end{align*}
\]
There exist no \(\chi_1, \chi_2\) satisfying the respective conditions. □
Remark 3.6. All six exceptional collections in (3.4) span the same torsion-free subgroup in $\text{Pic}(S)$ with generators $\mathcal{K}(1,0) = \mathcal{O}(1,0)[3,3]$, $\mathcal{K}(0,1) = \mathcal{O}(0,1)[3,2]$. We do not have a conceptual proof for this statement.

For a helix $E_*$ of period $n$ we introduce a matrix $\mathcal{M}(E_*)$ with entries consisting of the $\text{Ext}$-groups in the spires of $E_*:

\[ M_{i,j} = \sum_i \dim \text{Ext}^l(E_i, E_{i+j}) \cdot q^j; \ 0 \leq i,j \leq n-1. \]

Proposition 3.7. For the helices (3.5) we have:

\[
\mathcal{M}(\mathcal{H}_1) = \begin{pmatrix} 1 & 3q^2 + q & 3q^2 + q & 4q^2 \\ 1 & 3q^2 + 3q & 3q^2 + q & 6q^2 \\ 1 & 3q^2 + q & 6q^2 & 8q^2 \\ 1 & 4q^2 & 6q^2 & 6q^2 \end{pmatrix}
\]

\[
\mathcal{M}(\mathcal{H}_2) = \begin{pmatrix} 1 & 3q^2 + q & 4q^2 & 6q^2 \\ 1 & 3q^2 + q & 4q^2 & 6q^2 \\ 1 & 3q^2 + q & 4q^2 & 6q^2 \\ 1 & 3q^2 + q & 4q^2 & 6q^2 \end{pmatrix}
\]

In particular we see that all our collections have endomorphism dg-algebras with non-vanishing first and second cohomology groups.

Proof. The entries are found in the table given in Lemma 2.5.

Proposition 3.8. The $A_\infty$-algebra of the exceptional collection

\[(L_{-1}) \mathcal{O}, \mathcal{K}(-1,0), \mathcal{K}(-2,-1), \mathcal{K}(-3,-1)\]

is formal and moreover the usual product $m_2$ is trivial.

Proof. The $\text{Ext}$-groups of the collection $E_* = L_{-1}$ are all found in $\mathcal{M}(\mathcal{H}_1)$ from the previous Proposition. In fact we have:

\[
\left( \sum_i \dim \text{Ext}^l(E_i, E_j) \cdot q^j \right)_{i,j} = \begin{pmatrix} 1 & 3q^2 + q & 6q^2 & 8q^2 \\ 0 & 1 & 4q^2 & 6q^2 \\ 0 & 0 & 1 & 3q^2 + q \\ 0 & 0 & 0 & 1 \end{pmatrix}.
\]

In order to prove formality we check that the higher Massey products $m_k, k \geq 3$ of the collection $E_*$ vanish.

Using a standard argument (see [Sei08], Lemma 2.1 or [Leff02] Th 3.2.1.1), we may assume that $m_l(\ldots, id_{E_l}, \ldots) = 0$ for all objects $E_l$ and all $l > 2$. Now the third Massey product $m_3$ vanishes for grading reasons and the products $m_k, k \geq 4$ also vanish since our graded quiver has only 4 vertices.

The product of the two non-trivial elements of degree 1 vanishes since these elements are not composable. All other products are trivial for grading reasons.

Let $(E_*)$ be one of the collections in (3.4). By [BK], Theorem 2.10 the subcategory $(E_0, E_1, E_2, E_3)$ generated by the collection is admissible and has a right orthogonal $\mathcal{A}$, i.e. there is a semiorthogonal decomposition $D^b_{\text{coh}}(S) = (E_0, E_1, E_2, E_3, \mathcal{A})$.

Proposition 3.9. Right orthogonals to two spires of a helix are equivalent categories.

Proof. By transitivity it is enough to prove the statement for two consecutive spires. Denote $E_4 = E_0 \otimes \omega_S^{-1}$. Let $\mathcal{A}$ be the right orthogonal to $(E_0, E_1, E_2, E_3)$, and $\mathcal{A}'$ be the right orthogonal to $(E_1, E_2, E_3, E_4)$. We want to show that categories $\mathcal{A}$ and $\mathcal{A}'$ are equivalent. Denote by $\mathcal{C}$ the right orthogonal to $(E_1, E_2, E_3)$. Second decomposition $D^b(S) = (E_1, E_2, E_3, E_4, \mathcal{A}')$ implies $\mathcal{C} = (E_4, \mathcal{A}')$. First decomposition $D^b(S) = (E_0, E_1, E_2, E_3, \mathcal{A})$ is equivalent to $D^b(S) = (E_1, E_2, E_3, \mathcal{A}, E_4)$ by Serre duality, so $\mathcal{C} = (\mathcal{A}, E_4)$. Hence both $\mathcal{A}$ and $\mathcal{A}'$ are subcategories in $\mathcal{C}$ orthogonal to $E_4$: $\mathcal{A}$ is the left orthogonal and $\mathcal{A}'$ is the right orthogonal. So (left/right) mutations in $E_4$ establish the equivalence between $\mathcal{A}$ and $\mathcal{A}'$. □
We denote two equivalence classes of subcategories obtained by taking right orthogonals to \( \mathcal{H}_1 \) and \( \mathcal{H}_2 \) by \( \mathcal{A}_1 \) and \( \mathcal{A}_2 \) respectively. We note that a choice of a spire gives rise to a fully faithful embedding \( \mathcal{A}_i \to D^b(S) \).

**Proposition 3.10.** We have
\[
K_0(\mathcal{A}_i) = (\mathbb{Z}/5)^2 \\
HH_\bullet(\mathcal{A}_i) = 0 \\
HH^0(\mathcal{A}_i) = \mathbb{C}.
\]

In particular we see that \( \mathcal{A}_i \)'s are non-trivial.

**Proof.** We have
\[
\mathbb{Z}^4 \oplus (\mathbb{Z}/5)^2 = K_0(S) = K_0(D^b(S)) = K_0((E_0, E_1, E_2, E_4)) \oplus K_0(\mathcal{A}_i) = \mathbb{Z}^4 \oplus K_0(\mathcal{A}_i),
\]

thus
\[
K_0(\mathcal{A}_i) \cong (\mathbb{Z}/5)^2.
\]

For the homology we use the additivity theorem [Kuz09], Corollary 7.5:
\[
\mathbb{C}^4 = H^*(S) = HH_\bullet(D^b(S)) = HH_\bullet((E_0, E_1, E_2, E_4)) \oplus HH_\bullet(\mathcal{A}_i) = \mathbb{C}^4 \oplus HH_\bullet(\mathcal{A}_i).
\]

The statement about Hochschild cohomology is proved by the following approach of Kuznetsov [Kuz12]. Define
\[
\epsilon(F, F') = \min \{ p \mid \text{Ext}^p(F, F') \neq 0 \}
\]

For any increasing sequence \( a_0 < a_1 < \cdots < a_k = a_0 + n \) (\( n \) is the period of the helix \( E_\bullet \)), in our case \( n = 4 \) define
\[
\delta_{a_\bullet}(E_\bullet) = \epsilon(E_{a_0}, E_{a_1}) + \cdots + \epsilon(E_{a_{k-1}}, E_{a_k}) + 1 - k.
\]

Finally the anticanonical height of the exceptional collection is defined as
\[
h(E_\bullet) = \min_{a_\bullet} \delta_{a_\bullet}(E_\bullet)
\]

We now use the following result:

**Proposition 3.11.** [Kuz12] Let \( \mathcal{A} \) be right orthogonal to exceptional collection \( E_\bullet \). For \( k \leq h(E_\bullet) + (\dim S - 2) \) the natural map \( HH^k(S) \to HH^k(\mathcal{A}) \) is isomorphism.

For our helices we have
\[
h(\mathcal{H}_1) = 2 \\
h(\mathcal{H}_2) = 1
\]

and hence we see that \( HH^0(\mathcal{A}_i) = HH^0(S) = \mathbb{C} \).

\[\square\]
